## TREATMENT OF ECLAMPSIA\*

By FREDERICK W RICE, M D, NEW YORK, N Y

**E**CLAMPSIA is a rare condition when we consider the frequency of pregnancy, and always has been looked upon as one fraught with grave dangers for the mother and the child. We have no means of definitely determining the frequency of its occurrence, because its development is so greatly influenced by conditions of life to which the individual is subjected. Nor have we any evidence to show that the incidence of eclampsia is decreasing. Conditions of life today, which tend to produce bodily inactivity, over-eating and anxiety, favor its more frequent occurrence.

In the earliest medical literature, we find accurate descriptions of the occurrence of convulsions and coma during pregnancy. Eclampsia, however, must have been very rare in times past when conditions of life were more favorable for promoting the general health of women in pregnancy. In those days women were accustomed, during pregnancy, to continue to labor in the fields, or to work at household duties, eating a coarse, simple diet, with ample sleep and freedom from the worries and anxieties of the present day. Today, in our efforts to prevent eclampsia, we endeavor to improve and maintain the health of women during pregnancy by correcting habits of living injurious to their health, and, so far as possible, aiding them to acquire habits generally associated with that simple and healthful life of the past.

The fact that pre-natal care will, in most cases, prevent eclampsia is being demonstrated in all of the maternity hospitals which maintain pre-natal clinics. This fact is generally recognized throughout the profession among those practicing obstetrics. Yet, despite this knowledge of the value of pre-natal care, the number of cases of eclampsia is not lessening in general practice.

The hospitals which have been able, in recent years, to show more favorable results in treating eclampsia have profited by their own clinical ex-

perience, and, if there is to be any general reduction in the occurrence, or in the mortality, there must be a widespread dissemination and use of the facts thus obtained. The incidence of eclampsia in general practice is too uncommon to enable us to depend on our individual experience in treating this condition. It is quite evident, from the analysis of a large number of cases, that the value of the conclusion drawn from any special method of treatment, necessarily carried out in a limited number of cases, is questionable.

In considering the problem of the treatment of eclampsia, we will consider first some of the reasons for our failure to prevent its development, and second, results of the analysis of 222 cases of eclampsia.

An important factor in providing better pre-natal care lies in a clearer understanding of the nature, development and treatment of toxemia. At the present time there is too much confusion over the term toxemia and its many varieties.

From my experience, over many years, in teaching this subject, I know the difficulty the medical student has in grasping the significance and the practical importance of the various types of toxemia. As it is at present described in the various textbooks there is too much theory regarding its origin. A vast amount of clinical material is required to demonstrate the different phases in the various types. As a result, in many cases the essential points in diagnosing the onset of the mild toxemia, which if neglected may develop into eclampsia, are not made clear. If the subject could be taught from a more simplified classification we would have a better opportunity to emphasize that variety of toxemia which precedes eclampsia.

The term "toxemia of pregnancy," as used today, is confusing and unsatisfactory, since it is applied to several conditions developing during pregnancy which are clinically and pathologically unrelated. It seems to us that the term toxemia should refer only to the conditions which from

\*Presented at the Annual Meeting of the Medical Society of the State of New York, at New York, March 30, 1926

their origin, symptoms and pathology show evidence of being a toxic condition

Morning sickness, pernicious vomiting and acute yellow atrophy should no longer be considered under the term "toxemia of pregnancy"

Morning sickness is being looked upon today by the physiologists as evidence of slight reaction due to the establishment of the physiological changes of pregnancy. It is never a serious condition in itself, and occurs in more than half the cases of pregnancy. It was formerly considered under the term "toxemia," solely, because in some cases it developed into pernicious vomiting

Pernicious vomiting is no longer being considered by some authorities a toxemia. It was formerly so considered from evidence which is now known to be the result of inanition, or starvation alone. When it occurs, there is always a neurotic basis and, clinically, we get results in practically every case when treated early on the basis of a neurosis, and later, on the basis of an acidosis

Acute yellow atrophy is a condition which occurs about once in every 20,000 cases. Its diagnosis is positive only at autopsy. It is a condition not confined to pregnancy alone. Clinically, the majority of cases reported might be considered as pre-eclampsia

It may be that the elimination of these three conditions from the classification "toxemia of pregnancy" will meet with some objection, because of the authorities who still contend that they may be of toxic origin. Nevertheless, we think that there is sufficient clinical evidence to prove that the types recognized as pre-eclampsia, nephritic toxemia and eclampsia are the only conditions which should be classed under the term "toxemia of pregnancy"

In eliminating morning sickness and pernicious vomiting we do not mean to underestimate their importance because we feel that morning sickness, if neglected, is frequently the cause of pernicious vomiting, which in turn, must always be considered a serious complication. We feel, moreover, that in treating cases of morning sickness we have an opportunity, early in pregnancy, to establish for the patient a healthy regime, which is of great importance, if continued throughout pregnancy, in preventing the development of toxemia in the latter months of pregnancy

Our conception of the nature of toxemia is that it is a condition brought on by the failure of the body adequately to adjust itself to the new conditions incident to pregnancy when there are present added toxins from the intestinal tract, or a diseased kidney. Physiologists maintain that as pregnancy advances the physiological changes increase and more and more is demanded of such organs as the liver and kidneys but that these organs are able to accommodate themselves

to these extra demands of metabolism. When, however, there is an excess of toxins from the intestinal tract as a result of over-eating and constipation we soon see evidence of toxemia. And again, when a patient with diseased kidneys becomes pregnant the kidney may be unable to take on the extra demands and toxemia is more likely to develop. This latter condition is known as nephritic toxemia while the former is the pre-eclampsia type

We no longer consider the toxemia as caused by the toxins derived from the developing fetus or placenta but by defective detoxication and elimination caused by added toxins of protein nature absorbed from the intestinal tract

When our conception of toxemia was based on the theory that eclampsia was directly due to toxins from the fetus or placenta, immediate delivery of the patient was the chief aim of the treatment. Such radical treatment was, as we now know, a factor in increasing the dangers to both mother and baby

Clinically it is generally recognized that toxemia is prone to develop during pregnancy when there is evidence of over-eating or constipation, and especially when there is some degree of nephritis

It is a clinical fact that eclampsia develops most frequently in the first pregnancy. Liability to eclampsia during the first pregnancy is from 7 to 10 times greater than in subsequent pregnancies, when there is no complicating kidney disease. This protection against the development of eclampsia after the first pregnancy is due to the added powers of function of the liver and kidney brought about in taking care of the necessary physiological changes in the first pregnancy

From their origin, symptoms and pathology, pre-eclampsia and nephritic toxemia, which are liable to develop into eclampsia if untreated, should be considered as the toxemias of pregnancy

Although pre-natal care will enable us to prevent the development of pre-eclampsia, we must realize that despite this care toxemia will develop in a certain proportion of patients because of a previous nephritis

If we are to prevent the development of eclampsia the onset of toxemia must be recognized early and proper treatment instituted and thoroughly carried out

When toxemia develops we should endeavor, as quickly as possible, to determine the type. As the pre-eclampsia type is more prone to develop rapidly the treatment should be prompt and thorough. The nephritic type, developing more slowly, is more easily controlled by treatment and there is less danger of sudden change into the acute condition of eclampsia

Failure to prevent eclampsia is usually due to a lack of understanding of toxemia. In order to obtain results we must know the causes of

toxemia and have a thorough clinical knowledge of its development into the acute stage. This knowledge is necessary both for the early recognition of the toxemia and for the treatment.

We are able to recognize toxemia at its onset by albuminuria and increase in the blood pressure. In the majority of cases the rise in blood pressure may be observed before there is any evidence of albuminuria.

Both symptoms become more evident with the development of the toxemia, but the blood pressure, to a less extent, in the nephritic type as compared to the pre-eclamptic.

Added evidences of the toxemia soon make their appearance. Among these headache is very common to both types, but especially so in pre-eclampsia, while some evidence of visual disturbances and edema are distinctive of nephritic toxemia.

Pre-eclampsia is characterized by its appearance only during the latter half of pregnancy and its tendency, if neglected, is to develop rapidly with increasing severity of its symptoms—headache, rising blood pressure, appearance of edema, in some cases nausea and vomiting, diminished excretion of urine with increasing quantities of albumin and casts, epigastric pain, nervous excitement ending in convulsions and coma.

In nephritic toxemia there is less danger of toxemia becoming acute than with the pre-eclamptic type. When it does develop in such a manner it is almost identical with the clinical picture of pre-eclampsia. It is, however, most commonly recognized by its gradual progress, the symptoms being less pronounced and peculiar to itself, with increasing albumin, slight increase in blood pressure, edema more constant and increasing and resulting in the death of the fetus or inciting labor prematurely, but in some cases developing into eclampsia.

It is quite evident from the nature of toxemia of pregnancy that if we are to prevent its development we must lighten so far as possible the work of the liver and kidneys. We can only accomplish this in two ways: first, to lessen the amount of toxins absorbed from the intestinal tract, and secondly to aid in their elimination. Both methods are accomplished by the carrying out of the well known principle of pre-natal care.

As the toxins are formed from the breaking down of protein derivatives in the large intestines we limit their production and absorption by limiting the protein elements in the diet and preventing their accumulation in the large bowel. We aid in the elimination of toxins from the bowels by establishing regularity, from the kidneys by having the patient drink large quantities of water and from the skin by exercise and baths.

When symptoms of toxemia are evident we make use of these some principles in the treatment.

When the symptoms are observed early and are

of mild degree the removal of all protein from the diet and a thorough cleansing of the intestinal tract will, in most cases, clear up the toxemia.

When the toxemia is more pronounced, as evidenced by the symptoms, prompt and more thorough methods are necessary. In such cases the diet is limited solely to water, given frequently in large amounts to dilute the toxins and aid the kidney function. At the same time, the toxins are more thoroughly removed from the intestinal tract by cathartics, usually salines.

The irrigation of the colon in these severe cases is of the greatest value, and is necessary for several reasons. The first is further to help in the removal of fecal contents remaining in the large intestines, and the second reflexly to stimulate kidney function, to increase the fluids in the blood and to dilute the toxins by absorption from the large intestines. By having the temperature of the fluid in the irrigation maintained at 116 degrees F and the patient well wrapped in blankets we increase the elimination by stimulation of the sweat glands in the skin.

In the severest form of toxemia, eclampsia, the same principles are carried out in the treatment. But in eclampsia we have two added factors with which to contend—the convulsions and coma. By the administration of morphine and the avoidance of unnecessary interference we feel that we are able to limit the number of convulsions. The presence of the coma is a serious handicap in our efforts to aid elimination, as it prevents the administration of water through the mouth.

We make no attempt during the acute stage to induce labor or to interfere with labor if it develops spontaneously as it is prone to do. If there is delay during the second stage we do not hesitate to terminate labor by the use of forceps.

The patient must have constant and intelligent attention at all times. It is only by such means that we are able to obtain knowledge of the patient's condition and to prevent the development of complications which in many instances are, in themselves, the determining factors of our success. By a careful observation of the patient we are in a position to administer cardiac stimulation when indicated. In deep coma the lateral posture of the patient, allowing fluids to drain from the mouth, will prevent the development of pulmonary complications. The patient must be protected from injuries to the mouth during convulsions.

We personally do not make use of venesection unless there is evidence of need to relieve the heart strain. We consider it of no value in reducing blood pressure. Its value in reducing the toxins we do not consider sufficient compensation for the dangers in reducing the natural resistant

powers of the patient We have had no experience with transfusion in these cases and have avoided its use on account of the disturbance it might cause to the patient

We have recently analyzed the cases of eclampsia admitted to the Manhattan Maternity from the year 1906 up to the present year as well as the cases on the combined services at Bellevue Hospital during the past seven years

At the Manhattan Maternity Hospital during this period there were 130 cases of eclampsia in 27,450 deliveries

During the past seven years at Bellevue Hospital there were 92 cases of eclampsia in 14,620 deliveries on the combined services of New York University and Bellevue Medical College and Cornell University Medical College

Our aim in the analysis and study of these cases has been to obtain as many clinical facts as would be of value to us in our efforts to prevent and treat the condition

To obtain as many clinical facts as possible which might be of practical value we have considered the subject from the study of the cases under the following headings

- 1 Relation of eclampsia to age of patient
- 2 Incidence and mortality in primipara and multipara
- 3 Relation of onset to labor, and mortality in each type.
- 4 Relation to period of gestation
- 5 Seasonal effects on occurrence
- 6 Effects of multiple pregnancies
- 7 Repeated toxemias
- 8 Mortality at Bellevue Hospital
- 9 Mortality at Manhattan Maternity Hospital
- 10 Mortality in complete series
- 11 Mortality in relation to the number of convulsions, coma, pulse, temperature and blood pressure
- 12 Mortality in complete series classified as mild or severe.
- 13 Results at Bellevue Hospital in mild and severe cases
- 14 Results at Manhattan Maternity Hospital in mild and severe cases
- 15 Importance of blood chemistry
- 16 Classification and mortality from complications

17 Classification and results of clinic and emergency cases

18 Study of clinic cases during year 1925 at Bellevue and Manhattan Maternity Hospital

Of the predisposing factors, the following were considered age, primipara and multipara, period of gestation, season, previous toxemia or eclampsia and multiple births

#### OCCURRENCE AND MORTALITY IN PRIMIPARA AND MULTIPARA

	No	%	Deaths	%
Primipara	129	58%	26	20%
Multipara	93	42%	21	23%

Eclampsia was more frequent in primipara than in multipara with 58 per cent in the former as compared to 42 per cent in the latter In the British series this difference was more pronounced—70 per cent in primipara and 30 per cent in multipara

The mortality is higher in multipara than in primipara This fact is generally recognized and is undoubtedly due to the presence of some degree, of nephritis in multipara

#### RELATION OF ONSET TO LABOR AND MORTALITY IN EACH TYPE

	No	%	No Deaths	%
Ante-Partum	110	50%	27	24%
Intra-Partum	51	23%	11	22%
Post-Partum	61	27%	9	15%

Half of all the cases developed before the onset of labor There were more post-partum cases than intra-partum and the mortality was much less than in the combined ante-partum and intra-partum cases In the cases from the Obstetrical Service at Johns Hopkins Hospital the mortality was higher in the post-partum cases

#### RELATION OF ECLAMPSIA TO PERIOD OF GESTATION

Period of Gestation	24 to 28	29 to 32	33 to 36	37 to 40
No of Cases	25	41	53	96
Per Cent	11%	18%	24%	43%

The greatest number of cases of eclampsia developed during the last month of pregnancy During this period there were 96 cases, or 43 per cent, as compared to the previous month of 53 cases, or 24 per cent Where cases are neglected during pregnancy eclampsia develops

#### RELATION OF AGE TO ECLAMPSIA

No of Cases	Up to 20	21-25	26-30	31-35	36-40	41 on
220	45 or 20%	63 or 29%	54 or 25%	29 or 13%	27 or 12%	3 or 1%

We found that age had little or no effect as the incidence of eclampsia was greatest at the period of life when pregnancy is most common—between 20 and 25, but more common between 25 and 30 than under 20

early In almost every case receiving pre-natal care the eclampsia developed near the end of pregnancy or during the puerperium

#### SEASONAL EFFECTS ON ECLAMPSIA

No of Cases	Winter	Spring	Summer	Fall
220	56	60	53	51

It is apparent that the season has no effect upon the incidence of eclampsia

#### AFFECT OF MULTIPLE PREGNANCIES IN ECLAMPSIA

No of Cases	No Multiple Births	%
222	14	6.3%

The normal incidence of twins is about 1 in 80 In this series it was 1 to 16 There were 13 cases of twins and 1 of triplets

Zwefel in Germany with the same principles of treatment reports 94 cases with a mortality of 53 per cent Stroganoff claims to be able to reduce the mortality to 2 per cent, provided the cases are not neglected We think such a claim is justified in so much as the severity of the condition is undoubtedly greatly influenced by neglect The study of the cases in Stroganoff's clinic, published by Stander of Johns Hopkins Hospital, showed that the great majority of cases were mild in character, and over 70 per cent did not develop convulsions until after they were admitted to the clinic for treatment

In our series only 7 per cent of the cases had been under our care during pregnancy, and over 60 per cent developed convulsions before admission to the hospital Owing to the delay in getting the patients to the hospital a number died before we had opportunity to establish treatment

#### MANHATTAN MATERNITY HOSPITAL

	No Deliveries, 6,202 1906-1911			No Deliveries, 21,248 1912-1925		
	No	Deaths	Per Cent	No	Deaths	Per Cent
A P & Intra P	27	12	25%	60	12	20%
P P	7	1	13%	16	0	0%
Maternal Total	54	13	24%	76	12	15%
Fetal Total	54	31	57%	76	27	35%

#### PREVIOUS ECLAMPSIA OR TOXEMIA IN MULTIPARA

No of Cases	No with Toxemia or Eclampsia	%
93	17	18%

Of the 93 cases 17 gave a history of previous toxemia

#### COMPLETE SERIES TOTAL SERIES

	No Deliveries, 42,070 1906-1925		
	No	Deaths	Per Cent
A P & Intra P	168	40	23%
P P	54	7	12%
Maternal Total	222	47	21%
Fetal Total	222	101	45%

In the complete series of 222 cases there were 47 maternal and 101 fetal deaths, giving a gross maternal mortality of 21 per cent with a fetal mortality of 45 per cent

In 2,005 cases in the collected British reports the mean maternal mortality was 22.5 per cent, while the published reports of 247 cases from the obstetrical clinic of the Johns Hopkins Hospital from 1894 to July, 1924, the maternal mortality was 22.7 per cent In the collected series Dublin reported 204 cases with 10.29 per cent Stroganoff in Russia has reported 360 cases treated with a mortality of only 6.6 per cent, while

#### BELLEVUE HOSPITAL

	No Deliveries, 14,620 1919-1925		
	No	Deaths	Per Cent
A P & Intra P	61	16	26%
P P	31	6	19%
Maternal Total	92	22	23%
Fetal Total	92	43	46%

In the 92 cases admitted to Bellevue Hospital there were 22 maternal and 43 fetal deaths, giving a maternal mortality of 23 per cent and a fetal mortality of 46 per cent

At the Manhattan Maternity Hospital there were 25 maternal and 58 fetal deaths in the 130 cases admitted, giving a maternal mortality of 19 per cent and a fetal mortality of 45 per cent

During the years 1906 to 1912 at Manhattan Maternity Hospital our methods of treatment were based on the termination of the pregnancy as soon as possible Since that time we have followed the more conservative methods in general use in the maternity hospitals This change, although gradual, has reduced the maternal mortality from 24 per cent to 15 per cent, or a difference of 9 per cent, and the fetal mortality from 57 per cent to 35 per cent, a difference of 22 per cent

The severity of the condition is indicated by the severity of the symptoms The important symptoms of eclampsia are convulsions, coma,

pulse rate, temperature and blood pressure. The degree of edema does not seem to be of value in determining the severity of the condition.

The appearance of convulsions is an added strain on the heart already affected by the increased blood pressure and in cases having more than 10 convulsions we have a more serious condition to treat.

#### MORTALITY RATE IN RELATION TO NUMBER OF CONVULSIONS

No of Cases	Ten Convulsions or Less	Deaths	Above Ten Convulsions	Deaths
212	170	28-16%	42	15-36%

In 42 cases when there were more than 10 convulsions there were 15 deaths, a mortality of 36 per cent. In 170 cases with less than 10 convulsions there were 28 deaths, a mortality of 16 per cent.

#### COMA

	No of Cases	Deaths	%
Absent	8	0	0%
Semi-coma	91	8	9%
Deep-coma	76	30	40%

In 76 cases where coma was deep and persistent there were 30 deaths, a mortality of 40 per cent, and in 91 cases where the coma was not persistent there were 8 deaths or 9 per cent. In 8 cases where coma was absent there were no deaths.

#### PULSE RATE

	No of Cases	Deaths	%
Below 120	120	13	11%
Above 120	775	28	37%

In 75 cases when the pulse remained above 120 there were 28 deaths, a mortality of 37 per cent. In 120 cases when the pulse remained below 120 there were 13 deaths, giving a mortality of 11 per cent.

#### TEMPERATURE

	No of Cases	Deaths	%
Under 103°	174	23	13%
Above 103°	40	18	45%

In 40 cases the temperature was above 103°. In this group there were 18 deaths, giving a mortality of 45 per cent. While in 174 cases the temperature did not go above 103°. There were only 23 deaths, a mortality of 13 per cent.

#### BLOOD PRESSURE

	No of Cases	Deaths	%
Under 140	20	2	10%
140 to 200	108	14	13%
Over 200	38	8	21%

In the cases at Manhattan Maternity Hospital before 1912 the blood pressure was not generally taken, and in some of the cases which died shortly after admission there was no record of the blood pressure. In 38 cases when the blood pressure was over 200 there were 8 deaths, a mortality of

21 per cent. This would be greatly increased if we had a complete record of the severe cases which died without blood pressure being taken. In 28 cases when the blood pressure was below 200 there were 16 deaths, a mortality of 11 per cent.

When two or more of these severe symptoms were present we considered the case to be severe, and have classified the entire series under mild and severe.

In the total series there were 164 mild cases with 17 deaths, or a mortality of 10 per cent. There were 67 fetal deaths with a mortality of 40 per cent. In 58 cases classified as severe there were 30 deaths, a mortality of 51 per cent, and 34 fetal deaths with a mortality of 58 per cent.

#### TOTAL SERIES

##### MILD

	No	Deliveries, 42,070	
		1906-1925	
	No	Deaths	Per Cent
A P & Intra P	125	16	12%
P P	39	1	2%
Maternal Total	164	17	10%
Fetal Total	164	67	40%

##### SEVERE

A P & Intra P	43	24	55%
P P	15	6	40%
Maternal Total	58	30	51%
Fetal Total	58	34	58%

At Bellevue Hospital there were 66 mild cases and 26 severe cases. In the mild cases there were 6 maternal deaths, a mortality of 9 per cent, and 16 deaths in severe cases, a mortality of 61 per cent. There were 28 fetal deaths among the mild cases, a mortality of 42 per cent, and 15 deaths among the severe cases, a mortality of 57 per cent.

#### BELLEVUE HOSPITAL

##### MILD

	No	Deliveries, 14,620 1919-1925	No Deaths	Per Cent
A P & Intra P	45		5	11%
P P	21		1	4%
Maternal Total	66		6	9%
Fetal Total	66		28	42%

##### SEVERE

A P & Intra P	16	11	68%
P P	10	5	50%
Maternal Total	26	16	61%
Fetal Total	26	15	57%

In the Manhattan Maternity Hospital series of cases since 1912 there were 57 cases in the mild group with 4 deaths, giving a mortality of 7 per cent, and 19 severe cases with 8 deaths, a mortality of 42 per cent. As our methods of treatment are practically the same in both hospitals, our results in the mild cases were prac-

tically the same. The difference in the severe cases is no doubt due to the fact that at Bellevue Hospital the cases admitted as emergencies are more likely to have been neglected during pregnancy than those admitted to Manhattan Maternity Hospital.

pneumonia, which by more careful attention a great deal might have been done to prevent their development. It is important that we should be ready to give cardiac stimulation at the first evidence of cardiac weakness, as shown by increasing pulse rate. We feel that

## MANHATTAN MATERNITY HOSPITAL

### MILD

	No Deliveries, 6,202 1906-1911			No Deliveries 21,248 1912-1925		
	No	Deaths	Per Cent	No	Deaths	Per Cent
A. P. & Intra P.	37	7	18%	43	4	9%
P. P.	4	0	0%	14	0	0%
Maternal Total	41	7	17%	57	4	7%
Fetal Total	41	23	56%	57	16	28%

### SEVERE

A. P. & Intra P.	10	5	50%	17	8	47%
P. P.	3	1	33%	2	0	0%
Maternal Total	13	6	46%	19	8	42%
Fetal Total	13	8	61%	19	11	57%

## BLOOD CHEMISTRY

### 66 Cases Had Complete Report

	No of Cases	%	Average
N. P. N.	Increased in 34	53%	45 to 55 Mgms
Uric Acid	Increased in 46	70%	4 to 5%
CO <sub>2</sub>	Decreased in 20	30%	36%

No change in Urea, Creatinine and Sugar

In 66 cases we found complete reports on blood chemistry. We have found that the chemical analysis is of little value in determining the severity of the condition. Many cases developing from pre-eclampsia show no change in blood chemistry. Its value might be considered only as an aid in differentiating a nephritic origin from pre-eclamptic.

## MORTALITY FROM COMPLICATIONS

### Preventable

	No	%
Cardiac Failure	7	14%
Broncho-Pneumonia	15	31%
Cardiac Failure and Broncho-Pneumonia	2	4%
Sepsis	2	4%
Ruptured Uterus and P. P. Hemorrhage	2	4%

## OTHER COMPLICATIONS

### Non-Preventable

	No	%
Insanity	6	27%
Pleurisy	1	04%
Mastoiditis	1	04%
Placenta Previa	1	04%

In the study of the complications we have divided them into preventable and non-preventable. In the preventable we find conditions such as cardiac failure and broncho-

we have done much recently to prevent the development of broncho-pneumonia by maintaining the lateral posture of the patient and avoiding giving fluids by mouth until the patient is fully conscious.

Such complications as sepsis and ruptured uterus are not apt to develop when the conservative method of treatment is carried out.

## CLINIC CASES AND EMERGENCY CASES

	No	%
Clinic cases	19	7%
Emergency cases	203	93%

During the past seven years, of the 14,620 patients delivered on the combined services at Bellevue Hospital, 10,400 had registered and received pre-natal care. At the Manhattan Maternity since 1911 there were approximately 21,000 registered in the pre-natal clinic. Of these 31,400 receiving pre-natal care in both hospitals, 19 developed eclampsia—an incidence of 1 in 1,652 cases. Of these 4 were at Bellevue, an incidence of 1 in 2,600, and 15 at Manhattan, an incidence of 1 in 1,400.

As the organization and the management of the pre-natal clinics is the same in both hospitals, we should expect results in preventing eclampsia to have been more or less equal. Nevertheless, a larger number of cases developed at Manhattan Maternity. This fact was due to our inability to treat the toxemia patients within the hospital owing to lack of accommodations for such cases. At Bellevue we are able to send a large number of cases into the hospital for treatment. The results in

such cases are more satisfactory than when treatment must be given at home. During 1925 only 6 cases of toxemia could be treated in the hospital at Manhattan Maternity, while at Bellevue, 40 cases were treated.

Among these cases of eclampsia which developed while pre-natal care was being given, there was one maternal death. In 16 of the 19 cases the eclampsia was of the mild type—in 5 of these there was only one convulsion. The eclampsia developed at term in 17 of these patients. There were two stillbirths and one non-viable death. Thirteen of the cases delivered spontaneously, one was an elective Cæsarean section and five were delivered by low or medium forceps.

If we are to prevent eclampsia we must make sure that when toxemia develops it is treated as promptly and thoroughly as possible. This treatment can best be carried out in the hospital as we cannot depend on the co-operation of these patients in carrying out our instructions in the homes. There was evidence of toxemia in 61 patients.

During the year 1925 we found that 840 patients at the Manhattan Maternity registered in our clinics, made 6,038 visits to the clinic, an average of 5.5 visits per patient. At Bellevue Hospital during the same year at one clinic, 1,125 cases registered and made 4,127 visits to the clinic. Besides the visits to the clinic the patients in both hospitals are visited in their homes by nurses from the Maternity Center Association and Henry Street Settlement.

During 1925 the 840 patients registered at

Manhattan Maternity received 3,979 visits in their homes by these nurses. The average period in weeks for registering at the clinic for primipara was 30.7 weeks, and 31.7 weeks for the multipara.

### CONCLUSIONS

1. At the present time more attention is given to the treatment of eclampsia than to the prevention.

2. To lessen the incidence and severity of eclampsia a more general understanding of the nature and development of toxemia is necessary.

3. A simplified classification of the so-called "toxemias of pregnancy" would tend to focus attention on the more serious types, namely nephritic and pre-eclamptic types.

4. Prenatal care, if properly carried out, should prevent the development of toxemia in most cases.

5. In cases where toxemia develops despite routine observation of the patient we must recognize the symptoms early to prevent further development.

6. Cases developing despite prenatal care are more prone to occur at the end of pregnancy, and are of a less severe type.

7. If the symptoms do not respond promptly to treatment the patients should have hospital care.

8. The radical treatment increases the mortality rate for both mother and baby.

9. The most favorable results are obtained only when rigid attention is paid to the carrying out of every detail of the treatment.

## THE CANCER SITUATION IN THE STATE OF NEW YORK\*

By JOHN M. SWAN, M.D., ROCHESTER, N. Y.

*Chairman, New York State Committee of the American Society for the Control of Cancer*

Year	State of New York		State of New York excl. of N. Y. City	
	Total Deaths	Rate per 100,000	Total Deaths	Rate per 100,000
1921	11,163	105.9	5,590	116.7
1922	11,706	109.9	5,761	119.7
1923	12,257	113.9	5,970	123.6
1924	12,791	116.0	6,234	119.9
1925	13,117	117.4	6,345	119.8

The above figures, taken from the annual statistical reports of the New York State Department of Health, show the cancer situation as it exists today in this state. You will notice that the total number of deaths in the

state at large and in the state exclusive of New York City has progressively increased since 1921. The death rate per 100,000 population in the state at large has increased from 105.9 in 1921 to 117.4 in 1925. Exclusive of New York City the rate per 100,000 increased until 1923. In 1924 there was a drop and last year the rate remained the same. This apparent drop in the death rate per 100,000 population in 1924 is probably due to the increase in the estimated population in the state outside of New York City.

Can anything be done about this situation? The American Society for the Control of Cancer says that the first thing to do about it is to take cancer out of the realm of the mysterious, bring it out into the middle of the

\* Read at the twelfth annual meeting of the Fifth District Branch of the Medical Society of the State of New York, held at Watertown, October 14th, 1926.

room, and talk about it. This seems to us to be the logical point at which to begin the attack upon this enemy of the human race. The figures already quoted show that the disease is increasing, both in absolute numbers and in proportion to the population. Some observers, notably Hoffman, have even gone so far as to talk about "The Menace of Cancer." It seems to us that an explanation of part of the increase in the deaths from these diseases may be had by remembering that more people are living into the cancer age today than were living into that age 50 years ago. Nevertheless, the disease is apparently definitely increasing and if we are to succeed in reducing the incidence and the mortality, we must seek for a better understanding of it ourselves and we must try to instruct the layman in its manifestations so that by a system of co-operation between the patient and his medical advisor, the former may be gotten into the hands of the latter at the very earliest possible moment after the preliminary signs of malignant disease are discovered.

The beginning of the discussion, it seems to me, ought to take into consideration only those facts about cancer concerning which there can be no serious difference of opinion. In the first place, the cause of cancer is not known. We might as well admit this frankly as to try to conceal it. In spite of the work of Gye and Barnard, the cause of malignant disease is not known, although there are countless theories to explain it, none of which stands the test of scientific inquiry. Second, cancer is not a communicable disease. There is no case on record in the medical literature of a doctor or a nurse attending a cancer patient who has sustained a skin injury which has been followed by the development of a malignant tumor at the site of that injury. The recent case reported in the French *Annals of Pathological and Normal Anatomy*, has been carefully discussed editorially in the *Journal of the American Medical Association* for August 7th, and its fallacies pointed out. Third, cancer is not a constitutional or blood disease and there is no intention on the part of any medical man who makes a diagnosis of cancer to imply that the patient himself, or any of his ancestors, had ever lived an immoral life. In other words, cancer and syphilis have no relation whatever. Fourth, the American Society for the Control of Cancer is also on record as being of the opinion that cancer in the human family is not hereditary. We are well aware of the important and interesting studies by Maud Slye and others, and we recognize the fact that in the laboratory, strains of mice can be produced in which 100 per cent of cancer can be developed. But in the human family the conditions of reproduction

present important differences from those in laboratory animals. Humans are an extremely hybrid race and mating is not done in the same manner that it is conducted in the laboratory. Furthermore, there are very many people who have an unreasoning dread of cancer because some member of their family has died of it. These people live an extremely disturbed life. And we think that it is perfectly justifiable to assure such people that cancer is not hereditary. In other words, in the present state of our knowledge it is just as likely that the children of a mother who has died of cancer will not have cancer, as it is that they will have cancer. Fifth, most laymen and many physicians are of the opinion that a growth which is not painless cannot be malignant. This is not so. At the beginning cancer is almost never painful and it is only when the growth has developed so that the sensory nerve filaments become involved in the growth and are subjected to pressure that pain is experienced.

Cancer usually begins as a small, local, painless growth which is capable of complete removal and cure. If the patient waits until the growth has spread to the nearest lymphnodes, the chances for complete removal and cure are very much reduced, probably by 50 per cent, possibly by more. If the individual waits until the disease has spread beyond the nearest lymphnodes to those farther removed the disease becomes chronic, complicated by sepsis, and incurable. Cancer usually develops at the site of chronic irritation, on the lip of the pipe smoker, on the tongue of the individual with badly fitting artificial teeth or decayed, ragged teeth, at the pyloric end of the stomach in cases of chronic indigestion, in the rectum in cases of chronic inflamed hemorrhoids, in the uterus in cases of old cervical lacerations with low grade inflammation lasting for several years, in the breast after chronic cystic mastitis, in the skin in cases of senile keratosis and cases of pigmented moles. These lesions are those that we know as precancerous lesions and patients presenting them should always be looked upon as possible cancer patients. Not everyone who has these precancerous lesions develops cancer. But a woman with a lump in her breast should not be told to wait a month to see if the lump grows, nor to wait until it begins to bleed, before having that lump removed and examined microscopically. The patient presenting these lesions should be considered seriously and with care and every effort made to get rid of the disease before it becomes cancerous.

A physician once said that he believed nothing could be done to cure cancer, that he had sent patients to the surgeon who had removed the growths and the patients had died, that he

had sent patients to the radiologist for deep X-ray therapy and the patients had died, that he had sent patients for radium treatment and the patients had died. When asked how soon he sent his patients for those treatments, he said as soon as he was sure the disease was cancer. When one can be sure that a growth is cancer, it is already too late to expect to get a cure by any of these means, at least in the state of present development of our therapeutic measures. So, any sore in any part of the body that does not heal readily, any unusual discharge from any of the hollow cavities of the body, particularly if it is bloody, every lump in the female breast, persistent indigestion with loss of weight after middle life, warty growths or moles, particularly those subject to constant irritation, should always be considered potentially malignant and so treated. These conditions do not always mean cancer, but they demand serious consideration from the cancer viewpoint. The advertising quack and the patent medicine which claims to be able to cure cancer without the use of the knife are menaces to the solution of the cancer problem. Every effort should be made to discourage the activities of those engaged in deluding potential cancer patients into undertaking treatment by their methods.

The American Society for the Control of Cancer is of the opinion that if these facts can be impressed upon the laity and the profession, that the number of cases of cancer and the deaths from cancer may be reduced. We do not believe that we can abolish cancer from the human family, but we feel sure that the number of people succumbing to these diseases, particularly in the fifth and sixth decades, ought to be materially reduced.

The New York State Committee of the American Society for the Control of Cancer, at its annual meeting in December, 1925, voted to undertake an educational program in the State of New York, outside of Metropolitan New York, for the next three years, with the hope that, by impressing the facts just stated upon the profession and the laity, it might be followed by a diminution both in the total number of deaths and in the death rate. To this end it is proposed to establish a central office for the dissemination of information to all groups of people who desire to learn the facts. It is desired that an active committee be organized in every county of the state for the purpose of presenting these facts to those who desire to learn of them.

At the present time the majority of patients presenting themselves for operation at the various clinics in the state are inoperable when first seen. These patients should be seen before their growths become inoperable, and in order

to produce this result publicity is one of the strongest methods to employ. In a paper on carcinoma of the right segment of the colon by Mayo and Hendricks (*Ann Surg*, 1926, 83:357) the authors say "On account of the great interest manifested by the public in cancer and in fact in everything pertaining to the subject of disease and health, diagnosis is made early and operations are consequently more successful on external cancers that can be observed or felt by the physician or by the patient himself. This shows the advantage of the public discussions on cancer, cancer week talks, and the effectiveness of newspapers in aiding in this work of education. The surgical treatment of cancer is now much more effective than it was twenty years ago, the operations are much more thorough, and fixed and locally advanced growths involving the primary and secondary lymphatics and those with contact growths or metastases are treated by radium or other non-surgical measures, thus reducing unnecessary surgical mortality."

The State Committee hopes to be able to list the facilities in the state for the diagnosis and treatment of cancer, which at present are believed to be entirely inadequate, hoping that the information thus obtained will improve the situation in this respect. The establishment of cancer clinics under suitable auspices is a method which has the approval of many of the students of the problem. In July, 1924, the State Committee undertook the establishment of such a clinic in the City of Rochester as an experiment. It was desired to determine first, whether people would go to a cancer clinic, second, what percentage of patients who presented themselves at such a clinic actually had malignant disease, and third, what it would cost to conduct such a clinic. The clinic has, from the first, been conducted exclusively as an advisory and diagnostic enterprise, the patients seen being referred immediately to their own family physicians for the direction of whatever form of treatment was deemed advisable. The clinic completed its second year in July. It is open once a week. Any person who comes is examined and an endeavor made to reach a working conclusion as to the nature of the symptoms presented. Two hundred and eighty-five individuals came to the clinic during that period. Fourteen and one-half per cent of these individuals actually had malignant disease. This percentage checks very well with the experience of the public clinics held in Detroit in the eleven hospitals between January 25th and January 30th, 1926. Two thousand two hundred and forty two patients were examined in these hospitals, 21.3 per cent of whom actually had cancer (*Jour Amer Med Assoc*, 1926, 87:347). People will come to a

cancer clinic, they want to know whether or not they have cancer, and every effort ought to be made by us to give them a carefully thought out opinion. Such a clinic can be held in any community in the State of New York in which it seems desirable and practical, and in which the members of the profession desire to make a contribution to the solution of the cancer problem. Such a clinic can be operated for about \$350.00 per year.

In September of this year, the American Society for the Control of Cancer conducted a symposium at Lake Mohonk, to which one hundred of the most active students of the cancer problem, from all parts of the United States and Europe were invited. The outstanding accomplishment of this conference was the agreement by those present upon a statement which summarizes the basic knowledge of cancer and other malignant tumors as it exists today. While this knowledge is admittedly incomplete, the summary is considered as a satisfactory foundation upon which to proceed in an attack on the steadily increasing death rate. It is as follows:

"Although the present state of knowledge of cancer is not sufficient to permit the formulation of such procedures for the suppression of this malady as have been successfully employed for the suppression of infectious diseases, there is enough well established fact and sound working opinion concerning the prevention, diagnosis and treatment of cancer to save many lives, if this information is carried properly into effect. Although the causation of cancer is not completely understood, it may be accepted that for all practical purposes cancer is not to be looked upon as contagious or infectious. Cancer itself is not hereditary, although a certain predisposition or susceptibility to cancer is apparently transmissible through inheritance. This does not signify that because one's parent or parents or other members of the family have suffered from cancer, cancer will necessarily appear in other persons of the same or succeeding generation.

"The control of cancer, so far as this subject can be understood at the present time, depends upon the employment of measures of personal hygiene and certain preventive and curative measures, the success of which depends upon the intelligent co-operation of patient and physician. Persons who have cancer must apply to competent physicians at a sufficiently early stage of the disease, in order to have a fair chance of cure. This applies to all forms of cancer. In some forms early treatment affords the only possibility of cure. Cancer in most parts of the body can be discovered in a very early stage, and if cases are treated properly the prospect for permanent cure is good.

"The cure of cancer depends upon discovering the growth before it has done irreparable injury to a vital part of the body and before it has spread to other parts. Therefore, efforts should be made to improve the methods of diagnosis in these various locations and the treatment of the cancers so discovered.

"The public must be taught the earliest danger signals of cancer, which can be recognized by persons without a special knowledge of the subject, and induced to seek competent medical attention when any of these indications are believed to be present.

"Practitioners of medicine must keep abreast of the latest advances in the knowledge of cancer and learn the signs in order to diagnose the cases of cancer which come to them.

"Surgeons and radiologists must make constant progress in the refined methods of technic which are necessary for the diagnosis and proper treatment not only of ordinary cases, but of the more obscure and difficult ones.

"There is much that medical men can do in the prevention of cancer in the detection of early cases in the referring of patients to institutions and physicians who can make the proper diagnosis and apply proper treatment, when the physicians themselves are unable to accomplish these results. The more efficient the family doctor is, the more ready he is to share responsibility with a specialist.

"Dentists can help in the control of cancer by informing themselves about the known causes of cancer of the buccal cavity, especially with relation to the irritations produced by imperfect teeth and improperly fitting dental plates. They can also help by referring cases of cancer which they discover to physicians skilled in the treatment of cancer in this location.

"It may be doubtful whether some dentists fully realize the help which can be obtained from X-ray photographs which reveal not only the state of the teeth but the conditions of the bone surrounding them.

"Medical students should be instructed in cancer by the aid of actual demonstrations of cancer patients, and this to a sufficient extent to give them a good working knowledge of the subject.

"The most reliable forms of treatment, and, in fact the only ones thus far justified by experience and observations, depend upon surgery, radium and X-rays.

"Emphasis should be placed upon the value of the dissemination of the definite, useful and practical knowledge about cancer and this knowledge should not be confused nor hidden by what is merely theoretical and experimental.

"Efforts towards the control of cancer should be made in two principal directions, the pro-

motion of research in order to increase the existent knowledge of the subject and the practical employment of the information which is at hand. Even with our present knowledge many lives could be saved which are sacrificed to unnecessary delay."

The New York State Committee calls for volunteers for the work here outlined. Members of the medical profession can assist by accepting membership on the county committees and by agreeing to give practical talks to groups of lay people concerning the various forms of cancer. The Central office will furnish such volunteers with a lecture outline from which the talks may be prepared. It does not insist that those who give these talks shall adhere strictly to the points made in this state-

ment. But it does request them, if they believe certain of the statements require modification, that they indicate definitely that the modifications are the speaker's personal opinions and not the opinions of the American Society for the Control of Cancer.

In 1900 the deaths from tuberculosis per 100,000 population in the registration area of the United States was 201.9, in 1923 it was 93.6. In other words, in 23 years 108 lives out of every 100,000 people in the United States have been saved from destruction by tuberculosis. This result has been accomplished very largely by teaching people the facts about tuberculosis. May we not hope to produce a somewhat similar result if we undertake to teach the people the facts about cancer?

## INDICATIONS FOR THE RADICAL FRONTAL SINUS OPERATION WITH A REPORT OF CASES\*

By RICHARD TRAVIS ATKINS, M.D., NEW YORK CITY

**T**HIS paper is the result of a review of the histories of forty-two patients, on which the radical frontal sinus operation was personally performed. Most of these cases occurred on the Oto-laryngological Services of Bellevue Hospital and the New York Eye and Ear Infirmary.

The term radical frontal sinus operation, as used in this paper, implies the Killian operation, which has for its object the obliteration of the frontal sinus and removal of the adjacent ethmoidal cells.

The cases have been arranged in the following groups—

**GROUP I**—Operation urgent because of alarming symptoms. This group includes the cases complicated by intra-cranial or orbital involvement. As a rule these are acute cases of very marked virulence or acute exacerbations of chronic cases in which the bony walls of the frontal sinus have been softened or necrosed by prolonged suppuration.

**GROUP II**—Operation not urgent, but the indication positive. This group includes cases due to

- 1 Failure of intranasal treatment and operative measures to relieve (a) distressing symptoms such as headache, local tenderness, recurring edema of the upper eyelid, neuralgic pain, fever and discharge (b) frequent acute exacerbations which incapacitate the patient, (c) persistent foul discharge

- 2 Fistula

- 3 Recurrence following previous operations

- 4 Cysts and Mucocoeles

This group is made up of chronic cases and includes the majority operated on.

Intranasal measures ordinarily fail because of the anatomical structure of the frontal sinus. It is not always a simple cavity which is easily drained. Incomplete septa are often found which divide and subdivide the frontal sinus into compartments. Extensive recess formation is also found extending back over the orbit, and this may be divided into smaller recesses by septa, or it may be shut off from the main cavity by septa uniting the anterior and posterior walls. Mention should also be made of duplication of the frontal sinus and frontal bullae.

Recurrences following a previous operation are usually due to a reinfection, where there has been a failure of obliteration, or an incomplete operation.

It is in this group of cases that the X-ray is particularly valuable and no case should be operated on immediately because of intracranial com-

**GROUP III**—Operation exploratory. Doubtful indications because of uncertain diagnosis. This group includes new growths, orbital tumors simulating frontal sinus involvement and frontal sinusitis as a possible source of focal infection.

In the series of forty-two cases, six were operated on immediately because of intracranial complications. There were five brain abscesses, one of which was accompanied with cavernous thrombosis, and one meningitis. All of the cases also had orbital involvement consisting of exophthalmos, chemosis of the ocular conjunctiva, limitation of movement or fixation of the eyeball and swelling of the lids. Three were acute cases with no history of previous attacks, and three were acute exacerbations of a chronic process. All six

\* Read before the Annual Meeting of the Medical Society of the State of New York, at New York, March 30 1926

cases complained of severe headache and had a high temperature. Three cases had a stiff neck and a positive Kernig. Three cases showed fundus changes and one had a positive blood culture. There was one recovery.

The most interesting case in this group was an Italian girl, nine years of age, whose trouble began five days prior to admission to Bellevue Hospital with "a cold in the head." This was soon followed by fever, severe headache, pain in the left eye and vomiting. Later the eye became swollen. She was suddenly seized with a general convulsion, followed by a semi-stupor, in which condition she was brought to the hospital.

On admission there was a 103° temperature, some rigidity of the neck, a positive Babinski on the right and a suspicious Kernig.

The left eye showed exophthalmos, swelling and edema of the lids, and chemosis of the ocular conjunctiva.

There was a thin watery purulent discharge from the nose and marked edema of the mucous membrane on both sides.

While in the ward the patient had a convulsion limited to the left side, followed by a left-sided hemiplegia.

An immediate operation was performed consisting of a bilateral radical frontal. Both sinuses were filled with free pus under pressure, and the posterior walls were intact. Because of the intracranial symptoms, the posterior walls were removed and a thick creamy pus exuded from the right side. The dura was covered with a plastic exudate and the tension was somewhat increased. A small fistulous opening was found in the dura on the right side which was enlarged and a small subdural collection of pus evacuated.

The plastic exudate was very extensive covering the right frontal and extending to the temporal region, and this was uncovered.

The ethmoids were drained anteriorly through the usual ethmoidal incision.

Immediately following the operation the patient seemed brighter and there was no return of the convulsive seizures, but the temperature continued high and an exophthalmos soon developed on the right side. Both blood and spinal fluid were positive for hemolytic staphylococcus aureus and culture from the nose showed the same organism.

Three transfusions were given with no beneficial effect and the patient died ten days after admission.

This unfortunate case was undoubtedly one of primary infection of the fronto-ethmoidal labyrinth by the hemolytic staphylococcus aureus which rapidly spread through the lymph and venous channels to the meninges and cavernous sinus.

Another interesting case, a boy, age 17, was admitted to the New York Eye and Ear Infirmary

with the following history. Severe "cold in the head" two weeks before admission, which was followed by sharp shooting pains through the left eye and left side of the head. Later there developed swelling of the soft tissues about the eye which progressed rapidly causing the eye to bulge forward. He gave a history of frequent colds, and had received occasional treatment for sinusitis.

Examination showed edematous swelling of both lids on the left side, with the eye pushed downward and outward. There was marked chemosis of the bulbar conjunctiva. The eye movements were limited and there was a diplopia in all fields, especially when looking down. Fundus examination was negative.

The nose showed pus in the left middle meatus with considerable swelling of the middle turbinate. Antrum puncture revealed considerable thick, creamy pus.

Temperature 102° F on admission.

X-ray examination by Dr. Dixon showed cloudiness of all the sinuses on the left side.

Pus from the left antrum showed the presence of long chain streptococci.

*Operation*—Through an external ethmoidal incision a large quantity of creamy pus was evacuated and a drain inserted. This operation was done with the idea of affording drainage of the acute process and later performing a more radical operation.

The swelling rapidly subsided, the headache ceased and the temperature dropped to normal.

Four days later, however, there was a sudden rise of temperature to 104°, the headache returned and the patient became drowsy. There was some rigidity of the neck and a positive Kernig.

Another operation was immediately performed and this time the frontal sinus was opened and it was found filled with pus. The posterior wall was necrotic and a fistula found which led to the brain. About ½ ounce of foul smelling pus was evacuated. Tube drainage was established, and in a month's time the wound was healed and the patient discharged. It is now one year since the operation and the patient has remained entirely well.

This was apparently a chronic frontal lobe abscess which had been lighted up by an acute exacerbation of a chronic frontal sinusitis, and, as in all frontal lobe abscesses, the symptoms were vague.

There were eleven cases operated on because of the urgency of orbital complications. All showed swelling and edema of the lids, exophthalmos, chemosis, and in one case, there was gangrene of the conjunctiva. There was limitation of movement of the eyeball in six. All showed some temperature reaction, and in five cases it was septic-like in character, one case later developed a metastatic abscess of the hip. Headache and severe pain

were common symptoms. Necrosis of bone occurred in all but two cases, involving principally the floor of the frontal sinus, and in one case, I was obliged to remove a large part of the floor of the orbit because of necrosis. The anterior and posterior walls were both involved in one case, which disclosed an epidural abscess. Ethmoidal and antral involvement occurred in all of the cases.

Seven were acute in onset (less than three weeks) and four were acute exacerbations of a chronic process.

One case, an Italian boy, 19 years of age, was admitted to the New York Eye and Ear Infirmary with the history of headache and nasal discharge for two weeks, followed by swelling of the left eyelids, left side of the face, protrusion of the eye, high temperature, chills and delirium.

Examination of the nose showed a fetid, purulent discharge on the left side, and occlusion of the fossa by a bleeding, friable mucous membrane.

At operation the frontal sinus was found filled with pus and edematous mucous membrane. The ethmoids had been destroyed and were replaced by a soft friable granulation tissue which bled freely. The maxillary antrum was completely filled with a mass of tissue which proved to be a myelogenous sarcoma.

The sinus operation controlled the local suppurative condition, and after receiving the pathologist's report as to the nature of the growth, I resected the upper jaw. There was a recurrence, however, and the patient died three months later.

This was undoubtedly an inoperable case, but the secondary infection of the frontal and ethmoids obscured the true nature of the process which, in all probability, originated in the maxillary antrum.

In the second group there were ten cases operated on because of long standing suppuration, associated with frontal headache, tenderness, and in some cases swelling and edema of the soft parts about the orbit. The histories varied from eight months to twenty-five years.

All were incapacitated for work during the attacks and were left in a weakened condition after the acute stage had passed. In some cases the headache was almost continuous.

All had intranasal treatment which did not relieve or prevent recurrences.

There were four cases which showed fistula or sinus formations. Two followed an incision of a localized abscess about the orbit, and two followed the spontaneous rupture of an abscess. All of these cases had well marked signs and symptoms of frontal sinus involvement, and on probing, necrotic bone could be felt.

There were four cases operated on secondarily, because of failure of the primary operation to affect a cure. In all of these cases the indications were very apparent.

X-ray examination in most of the cases, in the second group, demonstrated why the cases did not get well.

One case of this group, a male, 39 years of age, gave a history of frontal sinus attacks over a period of seven years. Various intranasal operations had been performed consisting of removal of the middle turbinate, curettage of the anterior ethmoid cells and a rasp operation for enlarging the nasofrontal duct. This was followed by dense cicatrization so that it was impossible to probe or catheterize the frontal sinus. Every month or two the patient suffered with acute frontal pain and a slight edematous swelling, about the size of a dime, very tender to touch, over the lower and inner angle of the frontal sinus on the right side. This entirely disappeared with the pain, after a week's duration.

Operation revealed a small frontal sinus, with a deep orbital recess and a necrotic anterior wall immediately under the swelling.

Another case typical of this group, a male, 27 years of age, gave a history of recurrent attacks of frontal sinusitis over a period of ten years. Intranasal operations consisting of a submucous resection, removal of the anterior end of the middle turbinate and curettage of the anterior ethmoids failed to relieve the condition. The attacks were accompanied by temperature and were very exhausting. X-ray examination by Dr. Dixon showed a very cloudy left frontal and antrum. In the left frontal there was an area in the middle suggesting a semi-solid mass.

Operation revealed a large frontal, the anterior wall of which was necrotic over a small area, filled with free pus and a thick gelatinous substance. The mucous membrane was very edematous, entirely occluding the natural opening.

Another case, a male, 52 years of age, gave a history of frontal headaches over a period of twenty-five years. All of the sinuses had at one time or another been involved, and intranasal treatment had been fairly successful. Finally the right frontal became involved, following a "bad cold" and did not subside. Catheterization was easily accomplished, but irrigations failed to give relief. X-ray examination by Dr. Dixon showed a cell at the outer angle which was especially cloudy and a deep orbital recess.

Operation immediately relieved the condition through drainage of a blocked off cell near the external angular process.

In the third group there were six cases, especially interesting because of the doubtful nature of the pathology. Operation was, therefore, exploratory.

The first case, male, 37, had a marked exophthalmos on the left side. The eye was pushed downward and outward. There was no inflammatory condition of the soft parts, but a small, soft, tender swelling at the inner and upper orbital wall.

Examination of the nose showed a deviation of the septum to the right, no discharge, an enlarged middle turbinate on the left, with a bulging inward of the bulba underneath. Transillumination showed a dark left frontal and antrum. Antrum puncture was negative.

The patient gave a history of pain in the left frontal region three months before, which lasted about an hour, but no recurrence. There was no history of rhinitis. Three weeks before examination the left eye began to protrude and this gradually increased.

X-ray examination by Dr. Dixon showed the frontals to be of moderate size, right clear, left cloudy. There was a fault in the orbital ridge at the inner extremity. There was a thickening of the ethmoids and antra, particularly on the left side.

The Wassermann reaction was negative.

*Operation*—The frontal sinus was filled with edematous membrane and pus. The lower inner angle was necrotic, brick of which there was a walled-off collection of thick muco-pus. This proved to be sterile.

Because of the history and intranasal findings of this case, the possibility of a new growth was considered.

The second case was a male, 60 years of age, who had a marked exophthalmos on the right side. This had followed "a severe cold in the head" eight months before. The patient complained of frontal pain, headache, and a discharge from the right side of the nose.

Transillumination showed both frontals and right antrum dark. Right antrum puncture revealed considerable muco-pus.

On examination of the nose there was muco-pus on the floor of the right fossa, but a very sharp deviation of the cartilaginous septum prevented inspection, beyond the entrance. The left side was negative.

X-ray examination was made by Dr. Dixon and the following is his report. Right frontal sinus is very large, extending nearly to the outer angle. The left is smaller. They are both very cloudy, in fact, seem occluded. The left ethmoids and antrum are not very clear. The lateral plates show all the sinus regions cloudy. The sella turcica is quite deep and the dorsum looks suspicious of erosion, especially in front, but the clinoids are in situ and their outlines seem undisturbed, though the curve of the posterior comes well forward. No outline of a tumor can be made out in the orbit, but the plates give the impression of a tumor rather than suppurative disease.

*Operation*—Ether anaesthesia. Submucous resection, after which the right nasal fossa was freely exposed. The mucous membrane was markedly engorged and from the lateral wall a mass of granulation like tissue protruded, which almost filled the fossa. Radical frontal. The

anterior wall was soft and the interior of the sinus was filled with a granulating mass of tissue which was broken down. The floor was necrotic and the ethmoids were filled with a like material. All the structures bled freely.

Examination of the tissue removed showed it to be an epithelioma.

The patient developed pneumonia and died one week following the operation.

The true nature of the disease in this case was somewhat obscured by a secondary infection.

The third case presented obscure intracranial symptoms and was admitted to the hospital following an attack of facial erysipelas. The patient was a male, 31 years of age, and complained of pain in the right eye, frontal headache and a foul smelling discharge from the right side of the nose. Right sided antrum puncture revealed a softened naso-antral wall and considerable broken down foul smelling pus.

Eye examination showed an episcleral injection on the right side, slight exophthalmos, slight limitation of ocular movement and diplopia. The fundus showed veins distended and the discs slightly blurred.

Soon after admission to the ward, the patient vomited and the headache became more severe.

A lumbar puncture was performed and a clear fluid obtained under increased pressure, with a cell count of 50.

Neurological examination was made by Dr. Foster Kennedy, with the following report. Right sided facial weakness, peripheral type. Diminished abdominal and knee jerks on the left side. Questionable plantar response. Pulse 52, vomiting. All evidence points to intracranial abscess, but cannot localize with confidence. Do not believe exploration is indicated at this time.

Because of these alarming symptoms it was decided to explore the frontal and ethmoids on the right side.

*Operation*—The frontal was filled with pus and polypoid mucous membrane. There was no defect of the inner wall. A large area of dura was exposed and it appeared normal. The ethmoids were exenterated and the anterior wall of the sphenoid removed. The sphenoid was filled with a soft mass of friable tissue, but unfortunately no microscopical examination was made.

After the operation, the vomiting, dizziness and headache disappeared entirely. Subsequent lumbar puncture showed some increase in pressure, but less than before, clear, cell count 65, many lymphocytes, no organisms.

The improvement in the patient's condition lasted for about two weeks and then the headache and vomiting returned. Lumbar puncture entirely relieved him. At this time both optic discs were elevated about three diapters.

X-ray examination showed the presence of a hypophyseal tumor, and but for the X-ray find-

ings this patient would probably have been explored for a brain abscess. At the time of the operation the tumor had probably broken through the floor of the sella into the sphenoid and removal of the anterior wall relieved the intracranial pressure.

After the wound had healed, the patient left the hospital at his own request, promising to return for observation. Nothing further is known of his history.

Another case of this group was obscured by an accompanying syphilitic infection. There was a marked exophthalmos which anti-syphilitic treatment failed to relieve. Operation revealed a chronic fronto-ethmoidal suppurative involvement, and it was followed by a complete recovery of the local condition.

The fifth case was referred from the eye service because of an iritis that had not responded to treatment. All foci of infection had been eliminated with the exception of a chronic frontal sinusitis. The radical operation was performed and the iritis disappeared.

**Conclusion**—When establishing the indications for an operative procedure on the frontal sinus, the following must be considered:

- 1 The urgency of the symptoms. In a small proportion of cases, due to a virulent infection, complications occur in a very short time, which necessitate an immediate operation.

- 2 The nature of the sinus involvement. If here has been some previous operation which has failed, or if there is a fistula leading into the frontal sinus, the indication is plain.

Ninety-five per cent of all frontal sinus cases are relieved of their distressing symptoms without the radical operation, so that leaves a small proportion that need special study as to the indication for the operation.

X-ray examination helps us to determine the topography of the frontal sinus and very often

tells us why our patients are not getting well. Frontals with many recesses, marked horizontal development and other abnormalities cannot be drained successfully through the nose. These cases very often come to operation.

- 3 The condition of the nose. Have we been thorough enough in our intranasal treatment? It is a question largely of drainage.

- 4 The age, sex, social standing, residence and occupation must be taken into consideration before advising an external operation. Prolonged frequent treatments are impossible in some cases, and a radical operation is the easiest and most logical way out of the difficulty.

The question of deformity is frequently raised, but this is of minor importance when we consider the dangers of non-operative interference in these cases, and with the newer methods of plastic surgery we may hope soon to overcome this objection.

Since this paper was written, I operated on a young man who came to the hospital with a short history of pain in and about the left eye and nasal discharge. The temperature on admission was 106° F. There was a slight edema of the upper lid. WBC 16,000, 94 per cent polynuclears. The eye grounds showed a slight blurring of the discs on the nasal side. Left antrum puncture revealed muco-pus. X-ray showed a pan-sinusitis on the left side. Blood culture was taken and in twenty-four hours it was reported positive for hemolytic-streptococci, and the patient during this time had developed an arthritis involving the left ankle.

**Operation**—Pus under pressure in the frontal and ethmoids. There was a large deep orbital recess also filled with pus under pressure. The wounds were packed and left open.

This case belongs to the first group of indications.

## THE TREATMENT OF AEROGENES CAPSULATUS (OR GAS BACILLUS), INFECTION IN CIVIL LIFE\*

By JOSEPH TENOPYR, M.D., BROOKLYN, N. Y.

From the Surgical Division of the Kings County Hospital

**T**HE bacillus of gas infection was discovered by Welch and Nuttall in 1892. It is also commonly called the Welch bacillus, another name commonly used is the gas bacillus. I do not intend to burden you with an extensive review of the literature. It is the intent of this paper to call attention to the modern treatment of wounds infected with the Welch bacillus.

The first delusion which I wish to dispel is that the bacillus aerogenes capsulatus infection of wounds is a rare disease of civil life. That the

disease is common is self-evident from the series of cases on which this paper is based. In eight periods of four months each, we have treated twenty-four cases at the Kings County Hospital.

Before we enter upon the question of treatment of this disease, it is necessary that we shall have a very clear mental picture of the beginning symptoms of this disease, because the success of the treatment depends upon the early diagnosis. The diagnosis in order to save life and limb must be made in the first twenty-four hours after injury in the vast majority of cases. There is a small number of cases in which the diagnosis

\* Read before the Clinical and Surgical Association of Massachusetts, October 8, 1926.

may be delayed because of the non-virulence of the bacteria and the slowness of the development of the signs and symptoms. Doubtful cases must be carefully followed until the diagnosis of Welch bacillus is excluded or confirmed. These cases which at first appear to be relatively benign may assume a virulent course. Immediately upon suspicion of the diagnosis active treatment must be instituted.

The patient comes to the hospital with a wound which is contaminated with street dirt, or it may be a relatively clean gunshot wound. Wounds of the extremities may be, and often are, associated with fractures. The compound fracture is reduced and almost immediately the temperature begins to rise. This sudden rise in temperature should make one bear in mind the possibility of gas bacillus infection.

There are two very suggestive symptoms which appear very early. These are first, pain which is disproportionate to the amount of injury, and second, acuteness of intellect. At the end of twenty-four hours there is a dirty greenish gray membrane over the area of the wound. The odor is characteristic and can be detected upon entering the room of the patient. If the wound has been sewed up, the edges will be red, and there will be slight bronzing of the skin if the affected area is viewed in a good light. The dressings will be stained with a reddish tinged serum. There is no evidence of pus on the dressing. The bronzing of the skin usually precedes the crepitation which occurs when the tissues become infiltrated with gas and gangrene follows.

In order to prevent gas bacillus infection in wounds, we have made it a practise to take all cases of contaminated lacerated wounds to the operating room. Under general anaesthesia a debridement of the wound is performed. The term debridement has to my mind the suggestion that this form of treatment of wounds originated during the War. This is far from being so. The debridement of wounds was described by Dr. Martin Tinker of Ithaca, New York, in 1909, and practised by us at the Kings County Hospital from that time on.

The method consists of placing sterile oil into the wound and sterile compresses saturated with olive oil over the wound, then the skin is thoroughly cleansed with tincture of green soap followed by alcohol, ether and benzine, and then the skin is painted with tincture of iodine. The wound is then cleaned thoroughly with benzine, washing out all the olive oil. The wound is then carefully treated surgically, removing all the macerated and bruised tissue. If one feels reasonably certain that all the infected tissue is removed, the wound is closed without drainage.

Every wound so treated must be carefully watched for the early symptoms which I have described to prevent the calamity of losing a limb or even the tragedy of losing life. For when

there is extensive evidence of gangrene, which I have not particularly stressed as a symptom, it is impossible to prevent the loss of limb and our efforts are then concentrated upon saving life.

The serum treatment of gas bacillus infection is based upon the research work of Dr. Bull and Ida Pritchard of the Rockefeller Institute for Medical Research. Dr. Bull and his co-worker have discovered an exotoxin which circulates in the blood, causing a hemolysis of red cells. In their experimental work they found no bacteria circulating in the blood except in the terminal stages of the infection just before death. They developed an antitoxin serum which stopped the destruction of the tissues locally, and neutralized the toxin in the blood and stopped the destruction of the red cells. This serum has been used in the Kings County Hospital since 1917. Dr. Bull had his first successful case with me in that institution. Since that time we have been able to minimize the loss of extremities and have reduced the tragedies incident to this infection.

In our series of twenty-four cases we have learned that it is necessary to suspect gas bacillus infection very early in every case of a lacerated wound with or without fracture. We bent every effort to eliminate the possibility of this infection from the moment of the patient's admission to the hospital. When the debridement of the wound is performed, an anaerobic culture is made by placing a piece of the infected tissue into the bottom of a sterile test tube, and over this is poured from another test tube a quantity of melted agar. This is incubated immediately, and sometimes within three hours there is evidence of gas formation in the culture if the infection is present. The agar is disintegrated showing the formation of gas. This material for cultures is constantly kept in the operating room.

Another aid in the early diagnosis which we use is the X-ray examination, and bubbles of gas are found in the tissues very often six hours after injury.

The early clinical signs and symptoms, and the early utilization of laboratory investigation both pathological and roentological, have enabled us to institute serum treatment early. Immediately upon the diagnosis of the Welch bacillus infection we give the patient 200 c.c. of the tetanus perfringens antitoxin serum. This is repeated anywhere from six to twenty-four hours. If the wound had been closed by sutures, the sutures are removed, and wet hydrogen peroxide dressings are applied. Usually after 400 c.c. of the serum there is a drop in temperature and a decrease in the pulse rate, the gangrenous process has ceased to spread, and the patient has lost the septic appearance, and will generally tell you that he is feeling better—that is to say, the patient has improved clinically. If the gangrenous process has spread to such a point that amputation is necessary, it should be done at this time without delay,

because the complication most to be feared and most likely to occur is hemorrhage

The experimental observation of hemolysis made by Bull and Pritchard in animals is confirmed by our clinical experience in the matter of the destruction of the red cells. In most of our cases a marked anemia was indicated after the first twenty-four hours following injury by a blood count of three million red cells or less. One of the indications for repeating the dose of serum is the continuation of the fall of the red cells. If the red cells become constant in number, or begin to increase in number, we feel reasonably sure that the hemolytic toxin is under control.

Bearing in mind the destruction of red cells, it naturally follows that blood transfusions are indicated and should be resorted to early because there are other pathogenic organisms to which the patient may succumb and which are not affected by the serum. So it has become our practise that as soon as diagnosis of gas bacillus infection is made, to have the patient typed with some of his relatives with a view of blood transfusion.

In our series of twenty-four cases there were seven deaths which yielded a mortality of 29 per cent. In the seventeen surviving cases there were seven amputations. When these are analyzed one will see that five of these amputations were due to a delay of over twenty-four hours in the administration of the serum. Ten cases, or 42 per cent, recovered without amputation. The analysis of the seven deaths shows that they died from two to forty-one days.

Case 1—J A, male, age 23 years. Received a gunshot wound of the shoulder. He did not receive the serum until the third day. This is an example where the toxin had apparently weakened the wall of a blood vessel, and even though the process had ceased to spread, the damaged vessel gave way and the secondary hemorrhage occurred on the ninth day. Over a period of two days he received 680 c.c. of the serum intravenously. This case also teaches the lesson that secondary hemorrhage must be constantly kept in mind. His blood count was 2,934,000 and a hemoglobin of 60 per cent.

Case 2—M P, female, age 51 years, sustained injury to heel due to a firecracker explosion, the os calcis was fractured, the wound was thoroughly cleaned under general anaesthesia on admission. No culture was taken, and serum was not given until the second day. The patient died shortly after the administration of 200 c.c. of serum. There was difficulty in typing this patient. The blood count was 3,470,000, and hemoglobin was 50 per cent.

Case 3—J F, male, age 16 years, had a compound fracture of tibia. 200 c.c. of serum was administered within 10 hours after admission. He received 900 c.c. of the serum. He came to the hospital in extreme shock and died on the third day of pneumonia. On Sept 28, his blood

count was 3,712,000 and hemoglobin 60 per cent. On Sept 30, his blood count was 3,840,000 and hemoglobin 70 per cent.

Case 4—L L, female, age 27 years. An abortion had been attempted four days before. 200 c.c. of serum was administered within 20 hours after admission to hospital. She lived 30 hours in the hospital, the blood count was not taken.

Case 5—D F, female, age 58 years, had fractures of the right ulna and radius and of the left tibia, and a lacerated wound of the left knee. She died from broncho-pneumonia, 41 days after admission. 400 c.c. of serum was given second day, and an additional 200 c.c. of serum was administered two days later. The blood count was 4,240,000 and hemoglobin 85 per cent.

Case 6—F N, male, age 7 years, he had a fracture of the left femur, a lacerated left foot, laceration of the left kidney, and general peritonitis. 200 c.c. of serum was given within 22 hours after admission. Next day an additional 100 c.c. was administered. The blood count was 2,688,000 and the hemoglobin 60 per cent.

Case 7—G M, male, age 46 years. Came to the hospital four days after injury with a compound fracture of the radius and ulna, the forearm and lower part of upper arm were gangrenous, and the tissue crepitated anteriorly to the nipple line and posteriorly to the inner border of the scapula. A shoulder disarticulation was performed. 200 c.c. of serum was administered within 22 hours after admission to the hospital. Next day 400 c.c. more of the serum were given. On the following day 300 c.c. more of the serum were given. Patient died on the third day.

On close study of these cases it is quite evident that four did not receive their serum until thirty-six hours or more after injury. One case was cured of gas bacillus infection, but died 41 days later of broncho-pneumonia. One case received serum ten hours after admission, but never rallied from his shock. Myocarditis and pneumonia complicated the condition. One case was complicated by laceration of the kidney and peritonitis.

### CONCLUSIONS

Diagnosis can and should be made early both clinically and bacteriologically and by X-ray.

This study suggests the following rules:

1 All lacerated wounds to undergo thorough debridement immediately on admission to the hospital.

2 Anaerobic culture to be taken at time of debridement.

3 X-ray examination to be made within four hours after injury.

4 Serum treatment in full dosage to be given early intravenously, not less than 200 c.c.

If these rules are followed gas bacillus will be robbed of its terrors to the medical profession, and prevent the calamities and tragedies incident to this infection.

### NEW YEAR'S GREETINGS

The message of the physician is always one of Peace and Good Will to Men, for that is what he brings to those who "Sit in darkness and in the shadow of Death"

Those who are engaged in this noble work form a brotherhood whose members are bound together by a peculiar tie of intimacy and fellowship. Gone forever are the days of strife and discord among physicians, and now the doctor is the friend and companion of all his colleagues. Contact with

nature in her varied forms, especially those related to human life and vigor, creates a kinship of medical men closer than that among the members of any other profession.

The NEW YORK STATE JOURNAL OF MEDICINE, the voice of the organized medical profession of the State of New York, brings to every physician and to those who look to him for health and life, its best wishes for a Happy New Year.

## PROGRESS OF THE YEAR

As the Medical Society of the State of New York passes another mile stone on the Way of Progress, it may be well for us to look back upon the course of the past year, to view the present outlook, and to indulge in a vision of our future destination

Physicians during the past year have broadened their acquaintanceship with other workers who are traveling the same Medical Way toward the one destination of health. Workers in public health fields, like those in business lines, are divided into three great groups

1 Physicians, who are the producers or manufacturers

2 Departments of Health, who are the capitalists and financiers

3 Lay organizations, who are the publicity managers, the advertisers, and the salesmen

Physicians know that they have a necessary product which the people seek to buy, but the doctors have lacked the financial capital and the sales personnel to bring their product to the homes of the people. The past year has seen a happy understanding and co-ordination among all the great groups of health forces, the first fruit of which has been the passage of the Practice of Medicine Act. The new law was possible because of the perfect team work by the trinity of health organizations—the medical societies, the departments of health, and the lay organizations. Physicians have laid some of their irksome burdens on the shoulders of others who were fitted and willing to bear them. They conceded to the departments of health the right and power of the investigation and official control of diseases, and they recognized the peculiar field of usefulness of lay organizations in social, financial, and political fields. In return, the departments of health and lay organizations recognized the supremacy of physicians in the field of the practice of medicine, and the doctors have showed themselves

willing to assume its burden. Travellers along the Way of Medical Progress now are assured of mutual helpfulness and cooperation.

When we contemplate our present position on the Medical Way, prominent features that smite our eyes are the gaudy signboards pointing to alluring havens of rest and refreshment, where one may buy artificial thrills of imitation health. But everywhere along the Way are modest guide plates placed by physicians where all seekers of the Way to Health may read them,—and the people are giving increasing heed to them and are demanding the removal of the misleading signboards that disfigure the medical landscape.

Whither will our present medical course lead us in the future? When we have reached the crest of the hills which bound our present view, we will see other heights beyond and will adjust our ideals to new standards. Our immediate problem is, how far do we expect to progress in a day, or a month? What ideal do we expect to reach tomorrow, or next year?

Medical organizations will show the people the newer fields which are already under experimental cultivation, and will teach them to demand their fruits.

The medical societies will also teach the doctors the methods of cultivating the newer fields of practice. Doctors will seek to practice preventive medicine among those who are apparently well, and they will devise practical means to discharge their civic duties as physicians. They will define concretely the vague conception embodied in the words "The Medical Profession," and will allocate the practice of the various branches of civic medicine to specific societies or their committees.

The enduring nature of the items of progress made by the Medical Society of the State of New York is attested by the progress along similar lines made by its sister state societies, and by the American Medical Association.

## TABLOID NURSING INSTRUCTION

A little knowledge is a dangerous thing. While physicians consider that too much knowledge of an impractical sort tends to unfit a nurse to care for the ordinary physical needs of a sick person, they are equally sure that too little knowledge is positively dangerous.

What shall physicians say about the prospectus from which the following excerpts are taken?

"We have decided to inaugurate a course of instruction to consist of ten sessions, covering a period of three weeks, considering the ordinary nursing duties and demonstrating the usual appliances employed in the sick-room. It is not intended to do more than qualify those taking the course to intelligently carry out the physician's

orders, to use sick-room appliances efficiently, to keep accurate records, to minister to the personal comfort of the patient, and, most important of all, to create in the nurse that confidence that comes from knowledge and practice."

The trouble with such a tabloid course is that it creates in the nurse too much confidence in herself, especially since the prospectus continues "We will find employment for those who qualify, at \$35 weekly. This is a good opportunity for robust women, between 30 and 50 years of age, especially widows, who must earn a livelihood."

This training purports to create a class of "Instructed Practical Nurses!"

## DR GEORGE HENRY FOX, AN AUTOBIOGRAPHY

Thirty-five years ago Dr George Henry Fox was well known to medical students as a lecturer on diseases of the skin. He was always intensely serious, and to the medical students he appeared to dwell on the heights of unapproachable greatness as with unerring skill he read the cryptic characters spelled on the skin in scarlet papules, and pimples and wheals. Surely such a doctor had neither the time nor the inclination to consider the joys and commonplace experiences of common mortals! But time and close contact with Dr Fox have demonstrated his kindly humanity and confirm what he says about himself in his autobiography.

An autobiography reveals the kind of thoughts which hold the mind when it is not consciously directed to a specific task. Some men's thoughts unconsciously turn to golf, some to making money, some to pessimism and jealousy, and others to religion. Dr Fox, if we may judge by the incidents related in his autobiography, still thinks of the commonplace experiences which are common to men of all walks of life. He relates, for example, how seeing and hearing the opera Samson in Paris had recalled to him clearly his experience of sitting on the knee of his ministerial father and listening to Bible stories. He also tells the thrill which he felt at college when the class was reading from the Greek testament and he came upon a sentence which he recalled hearing his father recite to him in a playful demonstration of how to "recite a piece."

Dr Fox is evidently somewhat of a musician, or at least, he thinks along musical lines, for he says that he likes to stand on a Fifth Avenue corner and listen to the brass band of a parade, because he too played a horn in a band in his

younger days. His musical thoughts even led him to compose a new tune for "My Country 'Tis of Thee," which the reader may find on page 204 of his autobiography.

Dr Fox spent many months in Europe studying skin diseases, and there he met those who later became famous in medicine, surgery and other specialties, but the stories were always intensely human. He was doing laryngology in a Vienna clinic and as an older student he taught Dr George M. Lefferts, later professor of laryngology in the College of Physicians and Surgeons, and Dr Lefferts had confided to him his strong ambition to become professor of skin diseases in that institution.

Dr Fox has always nurtured a justifiable pride in his own family, and ancestry, and is president of a society of the descendants of Norman Fox, his father. Concerning such a society he says

"Nothing will do more to foster a just family pride and to increase that friendly feeling toward one another which is so desirable and which is so apt to lessen with the passing years. If some remote ancestor be selected as its patron saint the society is apt to be unduly large and unmanageable. It is much better to go back but a few generations and to get every descendant actively interested."

If doctors made a practice of writing their autobiographies, about all that most of them could record would be ordinary matters like those in the autobiography. When Dr Fox relates those everyday experiences which all persons feel, but fear to express, he pays an unintentional compliment to every physician.

---

## TESTS FOR ALCOHOL INTOXICATION

When is a person intoxicated, or drunk from alcohol?

What are the pathological conditions in intoxication, especially in its incipient stages?

What are practical tests for the detection of intoxication?

These questions are of grave importance in view of the great proportion of automobile accidents that are the result of intoxication. Court records reveal only a small proportion of the drunken drivers who are involved in automobile accidents, for only those who are in a far advanced stage of drunkenness are recorded as intoxicated. Every doctor who travels rural roads comes upon several scenes of automobile accidents early, not only from being called, but also because he happens upon them, as any other traveler does. He often sees drivers who are intoxicated as evidenced by the smell of liquor in their

breaths, and a few slight psychological signs, which, however, are seldom sufficient to convince a judge or jury that the patient was intoxicated beyond any doubt.

Some degree of shock and of fear and apprehension would usually result from the accident itself, and a physician would usually have difficulty in sustaining a diagnosis of intoxication under a sarcastic cross examination by an astute lawyer for the defense.

Medical literature regarding the pathological condition in alcoholic intoxication is meager and scattered and is not readily accessible to physicians. This is a field in which graduate education could properly be promoted by the Medical Society of the State of New York. The subject of alcoholic intoxication is analogous to that of ether anesthesia, and the two might well be considered together. What becomes of alcohol in the

blood? How long does it remain in the body? What are its progressive effects on the nervous system as it is absorbed and eliminated? Information regarding all these points should be readily available to physicians

Physicians desire to be informed especially about practical tests for the detection of intoxication and drunkenness. The tests are along two lines

1 Those for detecting the presence of alcohol in the body,

2 Those for diagnosing abnormal mental states associated with the alcohol

The meagerness or unavailability of knowledge regarding alcohol in the body is indicated by the appointment of a special committee by the British Medical Association to formulate tests for drunkenness (*Jour A M A*, Feb 13, 1926, page 496). There are scattered references to newer tests for the detection of alcohol in the blood and urine, but none seem to be standardized and generally accepted. What is needed is that some physiological laboratory shall investigate the effects of alcohol on the human body in the same way that Professor Yandell Henderson of Yale University has investigated the effects of carbon monoxide and developed practical methods of diagnosis and treatment

\* This much is generally accepted,—that alcohol

is absorbed into the blood and circulates as such, and is found in measurable quantities in the brain, liver, and other organs for several hours after it is swallowed, and its effects on the nervous system and mentality are characteristic and progressive in proportion to its amount circulating in the body. The work that needs to be done immediately is the development of quantitative tests both chemical and psychological that shall exactly express both the alcoholic content of the blood and the degree of the resulting mental abnormality. Since scientific research has disclosed the conditions in ether anesthesia and in carbon monoxide poisoning it should succeed equally well in alcoholic poisoning. The tests at first may be difficult and intricate, and require expert investigators working with special apparatus, but the history of all such tests is not only that they are progressively simplified, but also that physicians learn their application and use them as soon as they are practical and reliable. A long step in the solution of the alcohol problem will be taken when a physician can diagnose the amount of alcohol in the body and the resulting mental abnormality of the patient. The courts will welcome the day when a physician can testify regarding these points as accurately as he now can concerning the presence of diphtheria bacilli in the throat, or colon bacilli in drinking water

## LOOKING BACKWARD

### THIS JOURNAL TWENTY YEARS AGO

*The causes of colds* This Journal for January 1907 discusses the causes of colds in an editorial which does not mention infection, but assigns their cause to the steam radiator which was then coming into general use. The editor says

"The sufferers from colds are not those who live in the out-of-door air, but are those who spend a large part of the winter-time in an unnatural atmosphere. The air in offices, stores, theatres, factories, and dwellings, in this climate is bad. Its temperature is usually higher than is consistent with good health, each occupant inhales the materials that have come out of some one else's lungs, and the percentage of moisture in the air is much below normal. These defects are due to the defects of the modern heating appliances. It is a long step backwards, so far as healthfulness goes, from the fireplace of our cold-less ancestors to the steam-heated radiator of this catarrhal generation

"Of all the iniquitous machinery that has ever been contrived to destroy the weaklings and emasculate the strong the steam-heated radiator stands pre-eminent. Here is a thing which can be put in a room, and the more tightly the room is sealed against the inlet and egress of air the more efficient it is and the more is it vaunted as a successful heater. The furnace, which was cast out to give place to this thing, is eminently more

rational. Every cubic foot of air from the furnace that enters a room displaces a cubic foot, it will not work unless there is ventilation. And the old-fashioned stove and the fire-place all demanded ventilation, but the radiator works best without it

"Another defect of most modern heating apparatuses is that they dry the air. It has been shown that persons breathing abnormally dry warm air have the vital resisting power of their respiratory mucous membranes decidedly lowered and rendered susceptible to the complex of phenomena designated as cold. Thus we find in our fine modern system for preventing coldness the conditions conducing to colds. Examination of the air of rooms in the winter shows from five to thirty per cent less moisture than is present in the normal out-door air. Our in-doors winter population lives in an atmosphere so far below the point of saturation that evaporation is constantly and more rapidly than normal taking place from the skin and respiratory mucous membrane. A result of this evaporation is a sensation of coolness. It is not uncommon to find in an office a temperature of 70 or 75 degrees, or even higher, and yet a sensation of chilliness when the moisture is low, whereas in a kitchen, with boiling pots on the stove, a much lower temperature imparts a decided sense of warmth to the skin."

# MEDICAL PROGRESS

The Sterilization of Infected Wounds and Chronic Ulcerations by Periarterial Sympathectomy—Rene Leriche and R. Fontaine (*Annals of Surgery*, November, 1926, lxxxiv, 5) find that in chronically infected wounds, provided these wounds are not in contact with foci of osteitis or do not contain foreign bodies, periarterial sympathectomy is followed in five to thirteen days by absolute bacterial sterilization. Their investigations show that chronic ulceration—ulcer following burn, varicose ulcers, syphilitic ulcer, chronic post-traumatic ulcer, etc.—is always infected with a large variety of microbial species. The different dressings that are usually applied in these cases do not alter the bacterial flora, and arsenobenzol and insulin, even though they promote healing, do not modify the bacterial state of the wound. When the wound becomes sterile after periarterial sympathectomy, the slides show only numerous polymorphonuclear leucocytes in good condition and normal large mononuclears. The rapid sterilization is explained by a considerable afflux of leucocytes and red blood cells at the level of the ulcer. But all the results of periarterial sympathectomy are not due to a sterilization of the infected surfaces. It produces, in addition, an exaltation of the tissues' vitality, which brings about a rapidity of healing in an infected wound which exceeds that of a normal aseptic one. When the chronic infection has been overcome and the state of nutrition of the skin improved, the application of dermo-epidermic grafts aids in completing the restoration. The grafts "take" well in these cases. This method has been applied by the writer only to ulcers which had previously received antisymphilitic treatment.

In this connection a case reported in *La Riforma Medica*, September 27, 1926, by G. Broghio, is of interest.

A man of 42, soldier in the late war, who had been wounded by a projectile which traversed the leg from above downward in such a manner as to produce a comminution of the tibia and ankle bones. He was treated by immobilization which was followed by the expulsion of fragments of bone and sequestra with formation of fistulous tracts. The patient was left with ankylosis of the ankle with the foot in a semi-equinus position. Several months later there was an abscess formation at the back of the leg which left an ulcer of large dimensions and which could not be made to heal. Associated with this were intense pains which could hardly be endured. In time it became impossible for the patient to walk, owing to the pain

set up by bearing the weight on the limb. Eight years after the injury the patient was examined and his general condition and nutrition were found to be excellent. The leg was hypotrophic, semirigid, and flexed on the thigh, the latter being flexed on the pelvis. The large ulcer on the back of the leg had cicatrized in part but there still remained an elliptical loss of substance which secreted but little and was very painful. No pulsation of the femoral artery was felt in the upper thigh nor in the popliteal space. This find with the evidently trophic character of the ulcer led to the operation of periarterial sympathectomy, done by Professor Finzi under local anesthesia in Scarpa's triangle. The femoral artery, represented by a sclerotic cord only, was isolated for about 8 cm and the adventitia removed. The pains at once ceased, the wound closed completely and the patient resumed locomotion. In other respects the condition of the leg remained unchanged.

Headaches, with Special Reference to Those of Ocular Origin—George E. deSchweinitz, in a recent address (*Canadian Medical Association Journal*, November, 1926, xvi, 11), asserts that 30 to 60 per cent of the cases of functional headache are due to eyestrain. All types of heterophoria, either alone or associated with refractive errors, are headache-producing, and may have favorite areas of the cranium for their activities, but it should be emphasized that these are often only suggestive localizations—nothing more. The degree of dysfunction of the ocular apparatus which causes the headache may be trifling, and yet be as effective, often more effective, as a pain producer than when gross defects are present. The incidence of ocular headache does not depend alone upon eye-work at close range. Car sickness associated with headache, the shopping, cinema, and automobile headaches are in the majority of instances due to eyestrain. Many pure eyestrain headaches continue after the eyestrain has been corrected, and under these conditions the surroundings of the patient during working hours—glare, imperfect illumination, unhygienic conditions, lack of fresh air—should be investigated. True migraine is never, in the writer's opinion, due solely to eyestrain, although the latter is often an important factor in the complex etiology of this disease entity. A long list of reflex disturbances may be due to eyestrain. Vertigo, one variety being characterized by a sense of falling forward when walking in a crowd, associated with confusion of ideas,

drowsiness, insomnia, timidity, night errors, and evil dreams, pseudo-chorea, habit spasm, epileptiform convulsions, melancholia, and neurasthenia, flatulence and other forms of dyspepsia, intestinal indigestion and constipation, pains strangely and persistently situated in the nape of the neck, between the shoulder blades, in the precordium, at the end of the spine, and deep in the mastoid. This category could be further extended. Since such symptoms are frequently due to extraocular causes, it is highly important that a complete investigation be made from all standpoints in order to eliminate other causes, toxic or mechanical. It is the duty of the physician to recognize the relation of eye-strain to all of these allied phenomena, and by a careful history and examination to determine or eliminate it as an etiological factor.

**The Relation of Tactile Impression and Hearing Perception**—John Tyndall, more than forty years ago, stated that all the sense organs—sight, hearing, taste, and smell—might justifiably be classed as modifications of the sense of touch. Max Goldstein (*Laryngoscope*, October, 1926, xxxvi, 10) brings forward evidence from the study of embryology and the comparative anatomy and physiology of animals, both vertebrate and invertebrate, which gives support to this statement. He shows that the special sensory end-organs originate, like the nervous system in general, from the epiblast, and that the terminations of the sensory nerves are always to be found in cells of epithelial origin, while mesoblastic elements are secondarily added to them, that is, sight, smell, taste, and hearing are secondary differentiations of a diffused sense, the tactile sense. In Goldstein's investigations and functional hearing tests it has been found difficult to determine where an auditory impression ceases and tactile impression begins, or to what degree one sensory impression may be translated into terms of the other. It has been demonstrated that when one speaks into a rolled hollow cylinder of paper blocked at the distal end, a deaf pupil with the finger tips may receive by tactile impression the sound of the speaker's voice, repeating words, numbers, and names with a fair degree of accuracy. Deaf pupils, whose finger tips have become highly sensitized, are able to receive and repeat sentences heard through an ordinary megaphone, the distal end of which is spanned by a tense diaphragm of Whatman paper, and with which the tips of the fingers are in contact. There is much promise in the use of apparatus embodying radio and telephone principles for the amplification of sound, since it has been shown that a considerable percentage of congenitally deaf children have some residuum of hearing which is peculiarly sensitive to stimulation and education.

Since the introduction of such apparatus in schools for the hard of hearing, not only is scholastic accomplishment much simplified and increased, but there is a distinct improvement in sound perception in many pupils. Just how far it may be possible to substitute one sense impression for another still remains to be determined.

**Vaccination and Paresis**—K. Arnold and M. Kopp first mention our lack of knowledge of the determining cause of paresis, for factors other than spirochetic infection are concerned here. Recently there has been seen the coincidence of three distinct authorities in the discussion of the possible relationship between this sequela of syphilis and vaccination against smallpox. Luksch, a bacteriologist, in connection with the rôle of the vaccine virus in the production of a form of encephalitis, suggested that it might cooperate with the treponema in the genesis of paresis. Independently a psychiatrist, Daraszkievicz, expressed a similar opinion, with the alternate view that the development of vaccinal immunity might be the determining factor. A third to arrive at the same conclusions is H. Salomon. The author limits his article in the *Deutsche medizinische Wochenschrift*, October 22, 1926, to a discussion of the alternative of Daraszkievicz and takes up first the vaccinal immune body theory. He made experiments with victims of paresis and normal controls as follows: a gram of frontal brain substance was rubbed up to an emulsion with saline infusion, mixed with vaccine virus in different proportions, incubated for a short time, and then inoculated into the skin of a rabbit. The result was quite negative, the pustules developing as usual, in other words the vaccine had not been in any way altered by the admixture of paralytic brain emulsion. The experiments were repeated with serum substituted for brain substance and with the same negative result. The author then proceeded to investigate the possibility that the vaccine virus directly attacks the brain with production of the so-called syphilitic encephalitis. This could be tested only on rabbits and only along the general line of the ability of the virus to cause a brain lesion. The author has worked on this problem for many months, using many animals and varying the conditions in all possible ways, yet up to date has never succeeded, merely by cutaneous inoculation, in causing the least evidence of encephalitis.

**Focal Infection in Its Relation to Medical Problems**—Francis Ashley Faught, writing in the *American Journal of the Medical Sciences*, November, 1926, ccxxii, 5, voices his conviction that the value of the elimination of focal infection, instead of having been overdone, has not

yet begun to receive the attention its importance warrants. There is a failure of some specialists, especially dentists and rhinolaryngologists, to appreciate that a devastating focal infection may be present in the absence of demonstrable pus. The value of the removal of foci of infection depends upon the thoroughness with which the search for such foci is made and the completeness of their eradication. Periodic health examinations are valuable as a means of discovering unsuspected foci of infection. Autogenous vaccines are useful in the treatment of focal infections, especially those from the teeth or the tonsils, and particularly when the removal of a number of teeth is indicated. The following procedure is recommended. After selecting one or two teeth showing definitely diseased apical areas, the teeth in this region are thoroughly scaled and cleaned, including those to be removed. Immediately upon extraction, the tooth grasped in the forceps is held over a tube containing bouillon culture, and its apex cut off with a rongeur so that it falls into the culture medium. The tooth socket is entered with a small sterile swab, which is immediately rubbed over a blood agar plate or tube slant. The autogenous bacterin when prepared is administered at five to seven day intervals, according to the patient's reaction, until five or six doses have been given, when multiple extraction can be carried out with little danger of acute exacerbation of the secondary foci of infection. Cases are cited demonstrating the importance of complete removal of all foci of infection, the danger of multiple extraction of teeth, the close relation of focal infection to gastroenteric disease, and the influence of focal infection on the thyroid gland.

**Antiquity of Psychotherapy.**—Psychotherapy may be considered from the double viewpoint of unconscious and conscious. The unconscious practice, in which suggestion figures so largely, has always been more or less in vogue, the physician and charlatan often being quite deceived as to the modus operandi of the cure or recovery of the patients. But conscious psychotherapy is much older than is generally thought and Professor F. Kehler in an article on Psychotherapy in the *Klinische Wochenschrift* for October 22, 1926, quotes numerous examples from literature. Thus in 1783 K. P. Moritz established a magazine to be devoted to empirical psychology and laid down principles for psychotherapy. Esquirol employed the term "moral treatment," but quite in the sense of our psychotherapy, and almost at the same time Reil, who was first a surgeon and general practitioner and later an alienist, claimed that mental therapeutics should be practised not

only in insanity but in all sickness. The axiom "treat the patient and not the disease" which connotes psychic management of patients is very ancient. The germ of it is found in Celsus but it was perhaps first enunciated in modern times by Leupoldt, who was probably influenced by Moritz, quoted above. Freud and his disciples in their widespread application of psychoanalysis to history and biography have unearthed numerous others who recognized the necessity for psychotherapy, the latter part of the 18th and beginning of the 19th centuries representing a sort of new awakening of this idea. There was however some confusion, as when Pinel ascribed the bulk of insanity to affects, although we know today that this teaching is false and that most insanity is endogenous in origin. Zeller, writing a century ago, held that the reserve forces of the patient might be utilized to combat his disease. The author does not mention Mesmer as an active agent in the promotion of modern psychotherapy.

**Age Incidence of Rheumatism.**—J. Ross Snyder (*Southern Medical Journal*, November, 1926, 11) states that, although rheumatism occurs with about equal frequency in children and adults, the symptoms in the former are very unlike those in the latter. The same non-pus-producing streptococcus which causes marked joint symptoms in the adult displays an affinity for cardiac and nervous tissue in the child. The constitutional symptoms in the child are often exceedingly mild and pass unnoticed. Rheumatic invasion, which should be distinguished from rheumatic fever, may be so insidious that unless we admit a prefebrile or prodromal stage we neglect a great opportunity in preventive medicine. Every infant born with a family history of rheumatism should be regarded as a suspect. Such a child is often below par in weight, in color, and in texture of the musculature, he is a poor feeder, has a capricious appetite, is nervous, does not sleep well, but tosses, grits his teeth, or cries out. He is susceptible to colds, has an unstable, flighty temperature, which rises with a slight cold, a day of excitement, or overplay, he is easily fatigued. When these symptoms occur in combination they afford a definite classification of the child as rheumatic. If the child's activities are not stopped, more marked symptoms appear—stiffness of the neck, sore throat, "growing pains," overaction of the heart, even in sleep, and a constantly elevated temperature. At this stage, tonsillectomy and other corrective measures are likely to be disappointing, and the heart remains crippled. The problem presented by these children can be solved only by revamping pediatric literature so that it will

no longer teach that rheumatism, except in rare instances, does not occur in a child under three years of age. Infants are born with portals open to the entrance of infection, rheumatic and otherwise. It should be taught that the child born of rheumatic parents is potentially a heart case and should have regular medical inspection.

**A Peculiar Affection of the Liver Accompanied by Cholesterinemia**—A Edelman says that he has for several years past been familiar with an undescribed condition which may serve to throw light on some of the common affections. He has seen it mostly in men of the age period 35-55 years although it also occurs in women. The chief complaint of the patients is of neurasthenoid symptoms, such as lassitude and irritability. There is however a peculiar restlessness which may drive them to unusual exertion, as in the case of one man who felt impelled to a trip round the world. There are numerous subjective sensations as of pain and discomfort. The physician's eye is taken with what at first sight seems to be icterus but is found on examination to be xanthoma, or rather perhaps xanthelasma as there is no mention of anything beyond simple discoloration. The blood shows a marked increase in the cholesterin content and not only hypertension but rigid and tortuous arteries are found to be present. Cardiac hypertrophy is probably a sequence of the arteriosclerosis. The liver is sensibly enlarged and tender on pressure. The total number of cases thus far studied is sixteen. The author suggests that the liver is the original source of the disease process, the increase of cholesterin being due to the incapacity of the liver to secrete it from the blood. The other symptoms are referred to the presence in the blood of certain retention substances. There is a suggestion of a disturbance in the suprarenals in the asthenia and discoloration of the skin, and these bodies are known to be intimately concerned in some unknown way with the metabolism of cholesterin. The author is now engaged in writing a more complete account of this disease from a study of the literature of analogous affections.—*Wiener klinische Wochenschrift*, October 21, 1926

**Treatment of Acute Intussusception in Infants**—In a special article in the *Lancet* of October 9, 1926, CCXI, 5380, Gertrude Herzfeld emphasizes the importance of early diagnosis in intussusception in infants, as shown by the fact that operation within 12 hours is almost invariably successful, while in cases left 24 hours or longer the mortality is from 30 to 60 per cent. In order to detect the sausage-shaped tumor it may be necessary to make an

examination under complete anesthesia. The treatment nearly always involves opening the abdomen, as with the injection of fluids it is impossible to tell whether reduction is complete. The preoperative injection of saline solution subcutaneously in the axillæ or the loin is important, as these infants are always dehydrated. The child should be well warmed in bed for an hour before operation, the operating room should be kept at a temperature of 75° F, and the operating table should be artificially heated if possible. The anesthetic should be gas-oxygen with a minimum of ether, or ethyl chloride followed by ether. Operative success depends mainly on rapidity and extreme gentleness in handling. Reduction is attained by milking gently backward along the colon within the abdomen. The actual reduction gives trouble as a rule only in the last two or three inches on account of the great swelling and edema of the parts. At this stage the intestine should be brought out of the abdomen. Injury to the peritoneal coat may be prevented by surrounding the tumor with a moist swab and uniform pressure for 30 seconds, by this expedient reduction is often easily effected. The simple operation should never take more than fifteen minutes. When the intussusception is absolutely irreducible, resection gives the best results, though the prognosis is always grave. A lateral anastomosis between the ileum and transverse colon or between the two portions of the ileum is the most satisfactory way of dealing with the situation. Postoperative measures consist chiefly in the administration of fluids and the maintenance of warmth. The child should receive saline every four hours for 12 to 24 hours, and for the first three or four hours the foot of the bed should be raised. The temperature should be taken every three or four hours, unless it rises above 104° F tepid sponging is unnecessary. A little sugar and water may be given after 6 hours, then a teaspoonful of breast milk every two hours for another six to twelve hours, after which the child may be allowed to nurse for five to ten minutes every three hours. When resection has been carried out, feeding should be begun more gradually, consisting of albumin water only, for 24 to 36 hours. Postoperative vomiting is best treated by gastric lavage every six hours and the injection of glucose to maintain nutrition. Temporary paresis responds better to stomach and colon lavage than to stimulants. If enteritis occurs, a dose of castor oil is given with the usual medical treatment. Recurrence of the intussusception calls for immediate operation, which is not so serious as it sounds, for patients usually do well after a second operation.

# LEGAL

By LLOYD PAUL STRYKER, Esq  
Counsel, Medical Society of the State of New York

## THE SUPREME COURT OF THE UNITED STATES LIMITS THE PRACTICE OF MEDICINE

On the 29th of November, 1926, the Supreme Court of the United States, in the case of Samuel W Lambert against Edward C Yellowley, by a divided Court of five to four, handed down a decision as far reaching as any which that august tribunal has ever made.

In 1922, Dr Samuel W Lambert of New York City, admitted by the Court to be "a distinguished physician," applied for an injunction to restrain Yellowley, the acting Federal Prohibition Director, and other officials "from interfering with complainant in his acts as a physician in prescribing vinous or spirituous liquors to his patients for medicinal purposes, upon the ground that the quantities prescribed for the use of any one person in any period of ten days exceed the limits fixed by said Acts, or either of them"

In his bill of complaint, Dr Lambert's manifold qualifications and experience as a physician were set forth, and there was likewise stated his belief that in certain cases, including some subject to his professional advice, "the use of spirituous liquor internally as a medicine in an amount exceeding one pint in ten days is necessary for the proper treatment of patients in order to afford relief from human ailments," and further "that he does not intend to prescribe the use of liquor for beverage purposes"

Dr Lambert's bill of complaint further alleged that "to treat the diseases of his patients and to promote their physical well-being, according to the untrammelled exercise of his best skill and scientifically trained judgment, and, to that end, to advise the use of such medicines and medical treatment as in his opinion are best calculated to effect their cure and establish their health, is an essential part of his constitutional rights as a physician"

The writer can think of no more patriotic or courageous service ever rendered to the medical profession than Dr Lambert's effort to secure from the Supreme Court a decision upholding him and his professional brethren in their liberty to practice medicine To the writer it appears a grave misfortune, both to the medical profession and to the public, that Dr Lambert's contentions were not upheld How much of merit there was in them appears in the fact that four of the nine Judges of the United States Supreme Court, in a dissenting opinion of great cogency and force, have sustained this eminent practitioner of the healing art in the contentions which he advanced.

The prevailing opinion was written by Mr Justice Brandeis The argument of the prevailing opinion is

(a) That the Eighteenth Amendment prohibits "the manufacture, sale and transportation of intoxicating liquors for beverage purposes"

(b) That Section 2 of the Eighteenth Amendment confers upon Congress "the power to enforce the prohibition by appropriate legislation"

(c) That the limitation upon the amount of liquor which may be prescribed for medicinal purposes, is a provision adapted to promote the purpose of the amendment

(d) That that provision is not arbitrary, as appears "from the evidence considered by Congress which embodies, among other things, the lessons of half a century of experience in the several States in dealing with the liquor problem"

(e) That evidence disclosed that practicing physicians differ about the value of malt, vinous and spirituous liquors for medicinal purposes, but that the preponderating opinion is against their use for such purposes, and that among those who prescribe them there are some who are disposed to give prescriptions where the real purpose is to divert the liquor to beverage uses In amplification of these assertions, the majority opinion calls attention to the fact that "the American Medical Association, at its meeting in 1917, had declared that the use of alcoholic liquor as a therapeutic agent was without 'scientific basis' and 'should be discouraged,' and, at its meeting in June, 1921, had adopted a resolution saying 'reproach has been brought upon the medical profession by some of its members who have misused the law which permits the prescription of alcohol'"

The majority opinion makes constant reference to the different views entertained by the members of the medical profession as to the therapeutic value of intoxicating liquor It says, for example, that

"Congress, in deference to the belief of a fraction of the medical profession that vinous and spirituous liquors have some medicinal value, has said that they may be prescribed in limited quantities according to stated regulations, but it also has said that they shall not be prescribed in larger quantities, nor without conforming to the regulations, because this would be attended with too much risk of the diversion of the liquor

to beverage uses. Not only so, but the limitation as to quantity must be taken as embodying an implicit congressional finding that such liquors have no such medicinal value as gives rise to a need for larger or more frequent prescriptions. Such a finding, in the presence of the well-known diverging opinions of physicians, cannot be regarded as arbitrary or without a reasonable basis. On the whole, therefore, we think it plain that the restrictions imposed are admissible measures for enforcing the prohibition ordained by the Eighteenth Amendment."

Further pursuing this subject, the prevailing opinion calls attention to previous decisions of the Supreme Court, and continues

"From the authority of these cases Dr Lambert seeks to escape by pointing out that he is a physician and believes that the use of spirituous liquor as a medicinal agent is at times both advisable and necessary. He asserts that to control the medical practice in the States is beyond the power of the Federal Government. Of course his belief in the medicinal value of such liquor is not of controlling significance, it merely places him in what was shown to Congress to be the minor fraction of his profession." And further, that

*"High medical authority being in conflict as to the medicinal value of spirituous and vinous liquors taken as a beverage, it would, indeed, be strange if Congress lacked the power to determine that the necessities of the liquor problem require a limitation of permissible prescriptions, as by keeping the quantity that may be prescribed within limits which will minimize the temptation to resort to prescriptions as pretexts for obtaining liquor for beverage uses."*

Even without reference to the convincing logic of the dissenting opinion concurred in by four Justices of the United States Supreme Court, as the writer sees it, the prevailing opinion unwarrantably extends the powers of Congress granted under the Eighteenth Amendment to enforce its provisions prohibiting "the manufacture, sale or transportation of intoxicating liquors *FOR BEVERAGE PURPOSES*," it constitutes a dangerous extension of the police powers of the Federal Government, and an unwarrantable invasion of the powers of the States, and above all, is a reflection upon the entire medical profession, as it is based in part upon the assumption that there are so many physicians who, under the guise of prescribing liquor for their patients, would merely seek to evade the purposes of the law, and would aid in diverting such liquor "to beverage uses," that the medical profession can not be trusted with that which large numbers of them believe to be necessary for the alleviation

or cure of disease. In the last analysis, the prevailing opinion holds that Congress, and not the medical profession, has the power to determine what is proper and what is not proper, and what shall and what shall not be prescribed for disease.

In passing, the writer can not forbear from the reflection that no more powerful instance could be cited of the ill effects suffered by the medical profession, from a lack of unanimity in its ranks, than this decision of the Supreme Court.

We turn to the dissenting opinion by Mr. Justice Sutherland with strong approval, and with equally strong regret that one more Justice of this distinguished Court did not conclude to concur with him in his unanswerable views. Had this been done, the dissenting opinion, and not the prevailing opinion, would have been the law of the land upon this subject.

"Plainly," said Mr. Justice Sutherland, "Congress in submitting the Amendment, and the several States in ratifying it, meant to leave the question of the prohibition of intoxicating liquors *for other than beverage purposes* to the determination of the States, where it had always been. The limiting words of the Amendment are not susceptible of any other meaning, and to extend them beyond the scope of that meaning really is to substitute words of another and different import."

With impelling force, Mr. Justice Sutherland continues

"It is important also to bear in mind that 'direct control of medical practice in the States is beyond the power of the Federal Government' *Linder v. United States*, 268 U. S. 5, 18. Congress, therefore, cannot directly restrict the professional judgment of the physicians or interfere with its free exercise in the treatment of diseases. Whatever power exists in that respect belongs to the States exclusively."

In these words, the learned Justice has placed his finger upon the true crux of the whole question, i. e., Can Congress interfere with the professional judgment of a physician or curb its free exercise in the treatment of disease? It is at least some comfort to find that four of the nine judges answered that question in the negative.

Turning to the reasoning of the majority, the dissenting opinion continues

"We have the fact that Congress, acting upon a report of one of its committees made after exhaustive hearings, declared by statute that the prescription of malt liquors should be prohibited and the prescription of spirituous and vinous liquors should be permitted. Justifying such legislation, the committee had reported that the overwhelming evidence was to the effect that *malt* liquors

(not also spirituous and vinous liquors) had no substantial medicinal value. It is now said by the majority, at one point, that the preponderating opinion of practicing physicians is against the use of all three and, at another point, that only a minor fraction hold the other view. I am quite unable to assent to these generalizations. On the contrary, the impossibility of determining, from anything now before this Court, what is the preponderating opinion upon the subject, is very clear. An examination of the hearings before the House Judiciary Committee, cited as authority for the foregoing statements, shows that the inquiry there was directed to the question of the medical value of *malt* liquors and that the question of the medical value of the other liquors was not under consideration."

Furthermore, the dissenting opinion calls attention to the fact that a questionnaire had been sent out to one-third of the physicians of this country, and it brought "a reply from enough to make 21.5 per cent of the whole number of physicians in the country, and that a little more than one-half of those replying voted 'Yes' on the use of whiskey as a therapeutic agency, some of them, however, taking exception to the word 'necessary,' saying that no drugs were absolutely necessary." The American Medical Association, whose resolution of 1917 is referred to have filed in this case a brief as *amicus curiae*, challenging the conclusion which is drawn from that resolution and vigorously attacking the Act now under review as arbitrary and unreasonable. In 1924, the House of Delegates of the Association adopted a resolution expressing its disapproval of those portions of the Act "which interfere with the proper relation between the physician and his patient in prescribing alcohol medicinally," and the dissenting opinion further continues

"As the record now stands, therefore, we must begin this inquiry with the assumption that vinous and spirituous liquors are in fact valuable medicines, and it necessarily follows that, at least as an end as distinguished from a means to an end, the prescription of such liquors in good faith for medicinal use cannot be prohibited by Congress, since that body lawfully cannot legislate beyond the grants of the Constitution. The report of the committee and the hearings will be searched in vain to find any suggestion that the quantity designated by the statute is adequate or that the committee or Congress gave any consideration to that question."

"The naked question, then," continues the dissent, "simply comes to this. Conceding these liquors to be valuable medicines, has Congress power, under the constitutional provision prohib-

iting traffic in intoxicating liquors for beverage purposes, to limit their prescriptions in good faith, and consequently their necessary use, for medicinal purposes, to a quantity which, under the allegations taken as true, is inadequate for such purposes? To me the answer seems plain. If Congress cannot altogether prohibit the prescription for medicinal use, it cannot limit the prescription to an inadequate quantity, for obviously, in that case, *to the extent of the inadequacy*, the prohibition is as complete, and the usurpation of power as clear, as though the prohibition were unqualified. If the power exists to limit the quantity to a pint in ten days, it exists to limit the quantity to a tablespoon or a teaspoonful or a few drops during the same or any other arbitrary period of time, with the result in substance and effect that the definite limitation of the prohibitory power by the words 'for beverage purposes' vanishes altogether."

And further this vigorous dissent goes on

"It is said that high medical authority is in conflict as to the medicinal value of spirituous and vinous liquors and (hence) it would be strange if Congress lacked power to determine that the necessities of the liquor problem require a reasonable limitation of the permissible prescriptions. This observation does more than beg the question,—it indulges an assumption the exact contrary of that which the record conclusively establishes, for the limitation of quantity is not only unsupported by any legislative finding that it is reasonable, but it is in flat opposition to the only facts appearing in the record which bear upon the question of what is a permissible prescription, and, therefore, is without rational basis, resting alone upon the arbitrarily exercised will of Congress. I do not see how it can be held otherwise without completely ignoring the case as made and constructing and considering another and different case."

How serious an invasion of the power of the States to regulate the practice of medicine is the majority's interpretation of the Eighteenth Amendment and the legislation enacted under it appears from this language of the dissent

"By the legislation now under review, the authority of Congress is so exercised that the reserved power of the States to control the practice of medicine is directly invaded, to the illegitimate end that the prescription and use of liquors for medicinal purposes is prohibited. It is true that Congress has wide discretion in the choice of means to carry the granted power into effect, but the means not only must be appropriate to the end but must be such as 'are not prohibited, but consist with the letter and spirit of the Constitution.' *McCulloch v. Maryland*, 4 Wheat 316, 421. A grant of power to prohibit for

specified purposes does not include the power to prohibit for other and different purposes Congressional legislation directly prohibiting intoxicating liquor for concededly medical purposes, therefore, does not consist with the letter and spirit of the Constitution, and viewed as a means of carrying into effect the granted power is in fraud of that instrument, and especially of the Tenth Amendment \* \* \* The effect of upholding the legislation is to deprive the States of the exclusive power, which the Eighteenth Amendment has not destroyed, of controlling medical practice and transfer it in part to Congress. See *Hammer v. Dagenhart*, 247 U S 251, 275-276."

However much we may concur with the dissenting opinion, and approve of its logic, or may disapprove of the reasoning of the majority, it is the law of the land that the opinion of the five judges must prevail, and that of the four dissenting members of the Court cannot control. As in so many other questions wherein the

Eighteenth Amendment is involved, the importance of the decision far transcends any mere question relating to intoxicating liquors. The real question in this case is whether or not the Doctors may decide what is well for their patients, or whether that decision may be made for them by Congress. The Doctor is responsible for the treatment which he gives his patient, but his hands are now tied by Congress as to what that treatment may be.

As with a clarion call, that decision should arouse the medical profession to the importance of maintaining a united front for the preservation of their rights and for the protection of their sacred trust—the patient's health and life. Although Dr. Lambert failed by one vote of securing a decision upholding him and his brother doctors in what he and they believe to be the proper performance of their duty, it should in no wise derogate from the obligation under which he has placed the entire medical profession for his courageous endeavor to vindicate their rights and their liberty.

#### CLAIMED IMPROPER TREATMENT OF INFECTION OF FACE AND EYE

A physician was called to the home of a woman about seventy years of age. He found her in bed suffering from gripe. He prescribed the necessary medication for her condition and visited her daily from January 13th to January 20th, at which time she had recovered from her illness. At the time of his first visit he also found that she had an infection of the eye and she told the physician that she had been under treatment by an oculist for this condition, who had given her medicine for the same. This physician did not attempt to treat the infection but he noticed, when he continued to call upon her, that the infection appeared to spread to the other eye and extended downwards toward the mouth, the infection having the appearance of a pustular infection. When this infection commenced to spread he prescribed a 10 per cent argyrol solution to be instilled in the eyes and resinol ointment to be applied to the face. These applications were not effective in subduing the infection. He then prepared and had applied a Dakin solution. This likewise was not successful in controlling the infection. He last saw the patient on January 24th. On the following day he received a telephone call from the patient's daughter and was discharged from further treatment of the patient. At this time, however, he advised the discontinuance of the use of the Dakin solution and the return to the resinol ointment.

Nothing further was heard from this patient until the physician was served with a summons in an action instituted against him, the action being brought in one of the up-state counties.

In the complaint in this action it was charged that on January 13th the defendant was employed as a physician to treat and advise the plaintiff, that the plaintiff was in a weak physical condition, bedridden, and gradually became worse as a result of the defendant's treatment, that she began to decline and underwent great pain and exhaustion, was in a nervous condition and emaciated as the result of the defendant's failure to render her the proper treatment for her condition, that while under the defendant's care the plaintiff was caused to suffer great and unnecessary pain and mental anguish, that her condition grew progressively worse and it was necessary to call other physicians to treat the plaintiff. It was further claimed that the plaintiff was caused to suffer a permanent disfigurement of the face, her eye-sight was impaired and there had also been caused a drooping of the eyelids, which greatly disfigured her. The plaintiff sought twenty-five thousand dollars' damages for her claimed injuries.

On motion made on behalf of the defendant, an order was procured requiring the transfer of the action to the county in which the physician resided and in which the treatment was rendered. After the transfer of the action the plaintiff failed to notice it for trial or place it on the calendar or take any further steps in connection with the prosecution of the action. After the proper period of time had elapsed, a motion was made on behalf of the defendant to dismiss the action for lack of prosecution, which was granted.

# NEWS NOTES

## THE HARRISON NARCOTIC LAW

The Council of the Medical Society of the State of New York, at its meeting on December 9, passed the following resolution regarding the proposed amendments to the Federal Narcotic Act

WHEREAS, physicians alone are qualified by training and licensure to employ narcotic drugs which, under certain conditions, are the greatest boons to suffering man, and

WHEREAS, no rules or regulations can be promulgated by which the dispensing of these beneficent drugs can be standardized, but decision must be left to the judgment of the attending physicians if human suffering is to receive prompt relief, and

WHEREAS, already many physicians have concluded the hazard and jeopardy to their license and opportunity to practice medicine incurred by the multitudinous rules and regulations involved in dispensing narcotic drugs, is so great and imminent that they have permitted their registration to use narcotic drugs to lapse, and

WHEREAS, the public of necessity suffer in the end if the physician lacks equipment and facilities for proper and prompt relief of pain, therefore

BE IT RESOLVED, that the Medical Society of the State of New York petitions its Congressmen, individually and collectively, to oppose any amendment and revision of the Harrison Narcotic Law that would make more difficult the conditions under which physicians are obliged to work at present. It requests immediate and continued opposition to favorable action on bill HR-11612 and its companion, S-4085, on the following grounds

1 It would be an unwarranted hardship on the physician to deny him registration under the Harrison Narcotic Act for a period of from one to two years if convicted of any violation whatsoever of the Act, *no matter how technical and unimportant the offense may be,*

2 It is unnecessary to give collectors of internal revenue authority to refuse registration under the Harrison Narcotic Act to physicians whom such collectors believe to be narcotic addicts, because *the law of the State of New York provides for the withdrawal of the license to practice medicine from any physician convicted of being a narcotic addict,* and the amendment suggested in both of these bills makes no provision for notice and hearing before such refusal, nor for an appeal from the collector's decision,

3 It is an unfair precaution, and the imposition on pharmacists of an impossible task, to authorize and require that they *refuse to dispense narcotic drugs on any prescription issued by a physician* if the pharmacist is of the opinion that the physician did not issue the prescription in the course of his proper professional duties,

4 It must be conceded that physicians should be permitted to use their best judgment in deciding the character and type of treatment to be employed on any particular patient they have under their care and, hence, it would be entirely wrong for any law *to forbid absolutely and under any and all conditions whatsoever, the omnibulont treatment of narcotic addicts,*

5 It would be an inexcusable imposition to make physicians keep more records than are now required, of narcotic drugs administered and dispensed in their services to the public

The Committee on Legislation of the Medical Society of the State of New York has sent a copy of this resolution to each congressman

The Committee also suggests that the Legislative Committee of each County Medical Society influence the family doctors of the congressmen and senators to write to the legislators at Washington urging them to give serious consideration to this resolution of the physicians

## PUBLICATIONS OF THE DEPARTMENT OF HEALTH OF NEW YORK CITY

The Department of Health of New York City issues weekly and monthly bulletins which are of great value to physicians from the standpoint of scientific medicine, as well as that of public health. The New York State Journal of Medicine has frequently quoted items in which every doctor should be interested

These bulletins will be sent to any physician who will send his name and address to the Director of Health Education, Department of Health, 505 Pearl Street, New York City. Those who are already on the mailing list should renew their applications, for the list of recipients is being revised

## PRACTICAL LECTURE SERIES OF THE NEW YORK ACADEMY OF MEDICINE

The New York Academy of Medicine has planned a series of practical lectures to be given on Friday afternoons at five o'clock in the building at Fifth Avenue and One Hundred and Third Street. The lectures are free and are open to all physicians. The great interest shown in similar lectures under the auspices of the Medical Society of the County of Kings assures the success of the extensive course planned by the New York Academy of Medicine. The lectures are as follows:

Jan 7—The treatment of pneumonia David Riesman, Philadelphia

Jan 14—General infections by bacteria Emanuel Libman

Jan 21—Obstetrical problems in general practice John O Polak

Jan 28—Clinical aspects of common otological infections Samuel J Kopetzky

Feb 4—Clinical forms of syphilis George M MacKee

Feb 11—Treatment of cardio-vascular syphilis Harlow Brooks

Feb 18—Urology for the general practitioner J Bentley Squier

Feb 25—Surgical aspects of medical conditions John E Jennings

Mar 4—The diagnosis and treatment of intestinal obstruction John F Erdmann

Mar 11—Problems of the first year Herbert B Wilcox

Mar 18—Common diseases of the eye John M Wheeler

Mar 25—Surgical aspects of diseases of the thyroid Eugene H Pool

Apr 1—Pathological causes of human misconduct Max Schlapp

Apr 8—The role of climate in the treatment of tuberculosis James A Miller

Apr 15—Useful drugs in clinical practice Lewis K. Neff

Apr 22—Contagious diseases Shirley W Wynne

## ORANGE COUNTY

The Orange County Medical Society held its annual meeting on December 15 in the Goshen Court House. The retiring president, Dr Hoyle, devoted his brief paper to a consideration of preventative medicine.

Dr Mace, Assistant State Inspector of Rural Schools, spoke briefly, stressing the important work which can be done by the rural school physician.

The meeting was devoted principally to a discussion of the anti-diphtheria campaign. Mr Joseph Manahan, Executive of the Newburgh Public Health Committee, explained how, by employing modern business methods, the Newburgh Committee had "sold" the toxin-antitoxin treatment to Newburgh. He explained in detail the large organization employed in the work, and the "go-get'em" methods used. He related the part taken by the various volunteers, and then told the results of the campaign, which has resulted in the inoculation of more than 80 per cent of Newburgh children. He recommended that the system be tried in other cities.

The Society had already gone on record in favor of the State campaign, on recommendation of the committee minority.

Dr Edward S Godfrey, Director of the Department of Communicable Diseases, urged extension of the inoculation throughout the county.

Dr Distler briefly spoke of work accomplished in Middletown. Dr Thomas Gillson attributed many deaths to public ignorance of the worth of the toxin-antitoxin treatment. Dr Hulett traced the development of the treatment. Dr F

W Laidlaw, district health officer, noted difficulties in opening a city campaign as compared with work in rural districts. Dr Chappell gave practical remarks on treatment of young children. Dr Cuddeback recounted the progress made in Port Jervis.

Dr H J Shelley, Middletown health officer, reported that, granting good luck from now until January 1, Middletown will have completed its first diphtheria-less year on record. Not one case has been reported during the year.

Dr J D Mars told of unusual progress made at Florida, where the work has been under way for three years. At the completion of the drive in the near future, he said, 95 per cent of the children within three miles of the village will have been inoculated.

Dr Joseph S Lawrence, executive secretary of the State Medical Society, declared that in the last analysis the prevention of diphtheria rests upon the practicing physician, and to him falls the duty of being medical missionary. The Newburgh success, he said, resulted from the cooperation of the public with the physicians. Similar results may be accomplished elsewhere if the public will come half way, he stated.

In accordance with the resolution approving the campaign, Dr Northway-Meyer, the new president, appointed the following committee to speed the work in Orange County:

Drs L G Distler and Thomas L Gillson of Middletown, E G Cuddeback of Port Jervis, Charles E Townsend of Newburgh, and W W Davis of Chester.

The following officers were elected for the year 1927.

President, Dr Oscar N Meyer, Middletown, vice-president, Dr Harry F Murray, Port Jervis, secretary and treasurer, Dr H J Shelley, Mid-

dletown, board of censors, Dr M A Stivers and Dr L G Distler of Middletown, Dr W H Snyder, Newburgh, Dr E G Cuddeback, Port Jervis, State delegate, Dr J B Hulett, Middletown, alternates, Dr A B Chappell of Middletown, and Dr J D Mars of Florida

---

### ONONDAGA COUNTY

The regular meeting of the Onondaga County Medical Society was held in the Iliawatha Room of the Onondaga Hotel, Syracuse, on the evening of Tuesday, December 14th. It began at 6 30 o'clock with a dinner at which about fifty members were present. Over one hundred were present at the business and scientific session that was held after the dinner.

The following officers were elected for the year 1927.

Dr C E Coon was elected president. Other officers are Dr John G Buettner, vice-president, Dr George M Retan, secretary, Dr Gerald Cooney, treasurer, Drs H E Burdick and Dr N P Sears, censors, Dr Thomas P Farmer, delegate to the state convention, Drs Clyde O Barney and F S Wetherell, alternates, Drs H B Pritchard and Brooks W McCuen, delegates to the fifth district branch convention.

Dr George M Fisher, President of the Medical Society of the State of New York, spoke in praise of the successful culmination of the drive

by the Syracuse Memorial Hospital to raise \$2,500,000 for the establishment of a new building on University Hill just west of the campus. This building will be a part of the Syracuse University Medical Center. The hospital will be closely affiliated with the University and Medical School and the facilities will be available for teaching. It will also be available for the treatment of sick students.

Further plans were announced to build a contagious disease hospital for all infectious diseases and also a psychiatric hospital, both of which will be affiliated with the University Medical Center.

The scientific paper of the evening was given by Dr Francis Carter Wood of the Crocker Institute for Cancer Research, New York City, on the subject "The Blair-Bell Lead Treatment for Cancer." He developed the point that while the treatment may have virtue, no treatment has been found efficacious in all cases, or can be used in any case with a reasonable hope of recovery.

---

### SENECA COUNTY

The semi-annual meeting of the Seneca County Medical Society was held at the Willard State Hospital on October 14th. The following officers were elected for the year 1927.

President Dr L A Gould, Interlaken, Vice-President, Dr E P McWayne, Fayette, Secretary-Treasurer, Dr J N Frost, Waterloo.

The Society went on record as being in full sympathy with the State Anti-diphtheria Campaign. The report of Dr L W Bellows, chairman of the Committee gathering the Historical Data of the Society, was accepted and it was decided to publish this in book form. This report covered a history of the Seneca County Medical Society from 1810 to 1926 inclusive, biographies of Seneca County physicians from 1792 to 1926 inclusive, 282 biographical sketches and notes,

history of Willard State Hospital, and 55 biographies of its resident physicians, history of Seneca Falls Hospital from its founding, and the history of the Waterloo Memorial Hospital. It was decided to place a copy of the book in each public library in the county and also one in the State Library.

The scientific session followed an excellent dinner presided over by the host, Dr R M Elliott, Supt of Willard State Hospital. The principal address was given by Dr William H. Mitchell, of Rochester, on "Gynecology." Dr John A Lichty, Supt of Clifton Springs Sanitarium and President of the Ontario County Medical Society, was the guest of the Society and joined in the discussion of Dr Mitchell's paper.

---

### CHAUTAUQUA COUNTY

The Annual Meeting of the Chautauqua County Society was held at the White Inn, Fredonia, N Y, on December 15, 1926. The following officers for 1927 were elected.

President, Dr W D Wellman, Jamestown, 1st Vice President, Dr J F Foss, Dunkirk, 2nd

Vice President, Dr B S Swetland, Brocton, Secretary, Dr Edgar Bieber, Dunkirk, Treasurer, Dr C E Hallenbeck, Dunkirk.

Dr W D Johnson of Batavia spoke on "The Surgery of the Handicapped Patient."

# THE DAILY PRESS

## DIAGNOSIS OF AMAZEMENT

The New York *Herald Tribune* of December 11 has an item which conforms to all the standards that make news interesting. Two manhole covers at Seventh Avenue and Twenty-second Street blew off, each carrying a person with it. The first one carried a woman with it twenty feet into the air according to her own estimate, and only ten according to witnesses, but at any rate both the cover and the woman's leg were broken, as might have been expected, and therefore one element of the unusual was lacking in that item of news.

The other manhole cover ripped a man's right trousers leg from hem to waistband and turned the pocket wrong side out. A roll of fifty dollars that was in the pocket was never found,—at least no one admitted seeing it.

"The explosions coming within a minute," said the account, "caused a good deal of frightened running about, and in the calm which succeeded, the gathering of a crowd which taxed the resources of the police. Ambulances, fire engines,

the police emergency trucks, and the emergency wagons of the gas company, the electric light company and the telephone company were soon on the spot." All this, too, is commonplace news, for a New York crowd gathers at the least excuse.

Physicians will find the most interesting items to be the closing sentences. "Mrs C who had a broken leg, a scalp wound and possibly internal injuries, was taken to Bellevue Hospital. Mr C was treated for amazement and went to a tailor for repairs."

Amazement was an original diagnosis, and the reporter who made it did better than he probably realized. If the patient met an ambulance chaser, his amazement probably deepened into shock, and the loss of his trousers and fifty dollars caused mental anguish which could be soothed only by a verdict of ten thousand dollars. That is often the final stage of an accident whose only tangible effect is an amazement which in former days the victim would capitalize in only a thrilling story often told to incredulous listeners.

## CANCER REMEDIES

The search for a cancer cure will be stimulated by an offer of \$100,000 in prizes made by William Lawrence Saunders, Chairman of the Board of the Ingersoll-Rand Company. One half the sum will be given to the discoverer of the nature of cancer and the rest for a cure. The New York *Herald Tribune* of December 17, commenting on the offer, says:

"The prizes, which are to be awarded by the American Society for the Control of Cancer, will not appreciably stimulate research work on the disease which is now going forward in various institutions at a cost much greater than the amount of the award, those interviewed said. As a practical method of exploding bogus cures and stimulating interest in the cancer problem they

consider Mr Saunders' proposition well worth while."

The article quotes Dr Francis Carter Wood, Vice President of the American Society for the Control of Cancer and head of the Crocker Research Laboratory at Columbia University, as saying: "Doctors can now demand that quacks come forward and submit to an investigation or else forego their claims." But Doctor Wood was quoted as saying that he did not expect to live long enough to see the discovery of either the cause or the cure of cancer. On the other hand Dr David Stewart is quoted as saying that he believed the cure for cancer would be discovered soon and by a physio-chemist or bio-chemist rather than a doctor.

## SCORPION STINGS

The New York *Herald Tribune* of December 17 carries a lurid tale about scorpions which is ascribed to the Los Angeles Times. The article says that a Mexican investigator has perfected a serum "to combat the deadly bite of the scorpion which annually claims hundreds of lives, particularly among children." The article goes on to say:

"The scorpion is found most prevalent in the Huichol and Cora districts of the State of Nayarit, and as far as Durango City, in the State of Durango. Some sections of this district literally swarm with the insects, and cases have been recorded where small villages have been abandoned because of the great hordes of scorpions that have descended upon them."

"A woman of this city who had been stung by one of the insects and was already suffering the horrible pains and spasms that precede death from the bite, was administered a dose of the new serum. Immediately thereafter she exhibited signs of improvement, and in a few hours was pronounced out of danger."

This will be news to physicians. The scorpion "bites" with a sting in the end of its tail. Its

venom varies in strength from that of a wasp to a virulency that may possibly cause death in an extremely susceptible person. It has been well known that infections of the venom will produce immunity. Possibly scorpions may be so plentiful in certain parts of Mexico that a supply of serum would be desirable. However, the newspaper story bears the evidences of an exaggerated unscientific tale.

---

## TWO POEMS

The New York *Herald-Tribune* devotes a space to verses entitled "More Truth Than Poetry," by James J. Montague. The issues for December 9

and December 23 contain the following verses which are both truth and poetry, and are worthy of Hygeia.

### TO A MICROBE

No fear feel I, I merely smile,  
When threatened by a crocodile  
The tiger cannot make me run  
For I'm a man and have a gun  
But you, a frail and tiny germ,  
When on my trail can make me squirm  
When in your flight you crave repose  
Perhaps you light upon my nose,  
You make the spot forthwith your lair  
And I do not observe you there  
Your offspring hatch a millionfold  
And then I catch a frightful cold  
I'm but a man, you realize,  
You take advantage of your size  
On me to light unfelt, unseen,  
Malignant mite, to vent your spleen  
And so I say to you, "For shame!  
Why can't you play an honest game?"

### DUMB CREATURES

The dinosaur was bigger than  
The largest type of motor van  
He might have crushed a Ford beneath  
His double rows of jagged teeth  
A single wallop of his tail  
Would have destroyed a county jail  
A microbe is so very small  
That he cannot be seen at all  
He has no teeth, he has small strength  
And very little breadth or length  
But in a long forgotten war  
He fought and licked the dinosaur  
Which proves, if you and I were wise  
We would not think so much of size  
But if a dinosaur strolled by,  
In shuddering terror we should cry,  
And through a roaring river swim  
So we might get away from him  
But placidly the microbe stands  
Upon our lips or ears or hands—  
And though we're told that he is there  
It's very little that we care,  
And never shudder with affright,  
Which proves that we're not very bright!

---

## THE SPAN OF LIFE

Statistics show a constantly lengthening span of human life. The present average at death in the United States is 56 years, an increase of 5 years since 1910. The New York *Times* of October 15 comments editorially on this increase, and says:

"Health ideals seem to have taken hold in the United States judging from the number of dietitians who write books and the millions who buy them. Read as eagerly as fiction are stories of how to live long extracted from centenarians, of whom there were more than 2,000 in the country in 1920. Hygiene has ceased to be tiresome. It has become personal. Men of 70 affect juvenility. A weighing machine may be found in most bathrooms. Diet is the order of the day.

Fewer and fewer are they who dig their graves with their teeth. Everybody is wise about the alphabetical vitamins.

"Preventive medicine is interpreted by the well to be simple food, fresh air and exercise. For the sick, clinics and 'health centres' abound. Frequent examinations to determine whether anything is wrong with the human machinery are now the fashion. After middle age men and women are making Death keep his distance and are living useful and happy lives. 'Give me health and a day and I will make the pomp of emperors ridiculous,' said Emerson."

The object of the Medical Society of the State of New York is that the people "might have life and that they might have it more abundantly."

# BOOK REVIEWS

**PEDIATRICS** By Various Authors Edited by ISAAC A. ABT, M.D. Volume 8. Octavo of 1102 pages, with 388 illustrations, and General Index to Volumes I to 8. Philadelphia and London, W. B. Saunders Company, 1926. Cloth, \$10.00 per volume. Sold by subscription.

This eighth volume is a fitting climax in bringing to a close this pre-eminent work on the Diseases of Children, and with the General Index to Volumes I to VIII, makes its information readily available. To the specialist and to the general practitioner it should make the appeal of being the best work on the subject from the American standpoint with which the reviewer is familiar. From the mechanical standpoint the paper is good, the type is clear and easy to read, and the illustrations which are many, are distinct. From the scientific standpoint each subject is dealt with by an author who is a master in his field, and the result is a wealth of detail that makes it a storehouse of information for reference. It is no less a guide in the matter of treatment which is taken up in the same complete way, and the General Index makes it easy for the busy man to use it in a practical way.

Specifically Volume VIII deals with Diseases of the Skin, Edited by Oliver S. Ormsby, M.D., who has seven other skin specialists as his collaborators, Ear Diseases in Childhood, by George E. Shambaugh, M.D., Ocular Diseases of Infancy and Childhood, by Casey A. Wood, M.D., Hospitals for Infants and Children, by John M. Dodson, M.D., and Richard E. Schmidt, F.A.I.A., Medico-Legal, by James P. Simonds, M.D., Tumors of Infancy and Childhood, by Oscar T. Schultz, M.D., Encephalitis, by Leslie B. Hohman, M.D., and Animal Parasites, by Henry Baldwin Ward, Ph.D., Sc.D. Of these the articles on Diseases of the Skin, Hospitals for Infants and Children, and Tumors, are especially noteworthy. ARCHIBALD D. SMITH

**A MANUAL OF NORMAL PHYSICAL SIGNS** By WYNDHAM B. BLANTON, B.A., M.D. 12mo of 215 pages. St. Louis, C. V. Mosby Company, 1926. Cloth, \$2.50.

Theoretically, a manual of normal physical signs might seem a refinement for the beginner and an implement which would add to his troubles rather than afford a means for simplifying his work.

But the days of simple inspection, palpation, percussion and auscultation have passed away and it now requires something over 200 pages, of rather close printing, to outline the procedures which are to be carried out for a complete physical examination. This alone is sufficient testimony to the increases in number of details which confront the beginner, as compared to the days of Austin Flint.

Dr. Blanton has given a very complete outline of these details, beginning with the discussion of the mechanics of physical signs, amplifying sufficiently, but never beyond the outline stage.

At the end of the chapters, there are notes for further reading, and an adequate index is provided.

The manual will be of very great value for the physician who needs to make, for his daily use, a new and more complete outline for routine physical examination.

L. C. JOHNSON

**SURGICAL ANATOMY OF THE HUMAN BODY** By JOHN B. DEEVER, M.D., Sc.D., LL.D., F.A.C.S. Second edition in three volumes, thoroughly revised and rearranged. Volume I. Scalp, Cranium, Brain, Face, Mouth, Throat, Organs of Special Senses. Quarto of 551 pages with illustrations. Philadelphia,

P. Blackston's Son and Company, 1926. Full fabricoid, \$36.00, payable \$12.00 upon receipt of each volume.

Some twenty-six years ago there appeared the first edition of "Surgical Anatomy" by Dr. John B. Deaver. The work was in three volumes, carefully compiled, beautifully illustrated with mostly original drawings and apparently complete in every detail. Despite the fact that this original work is fairly modern and useful today, the author undertook the labor of revision with the idea of better fitting the new edition to the advances of modern surgery and at the same time to rearrange the contents into a more systematic scheme.

The first volume of the new edition is now with us. It contains the surgical anatomy of the scalp, cranium, brain, face, mouth, throat and organs of special senses.

The surgeon or student can see at a glance the advantage of the new arrangement when compared with the first edition. For example the entire head is complete in the first volume. In the first edition it was scattered between volumes one and two. Many parts on the brain and spinal cord have been rewritten. As the modern medical student is more familiar with the Basle anatomical nomenclature the English equivalents have been added in parenthesis throughout.

This work has always been regarded as a most substantial contribution to medical literature. An enthusiastic welcome is due to this new edition from the pen of the master teacher and surgeon.

R. F. BARBER.

**CLINICAL PEDIATRICS** By JOHN LOVETT MORSE, A.M., M.D. Octavo of 848 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1926. Cloth, \$9.00.

Any one who knows Dr. Morse would expect a textbook from his pen to be eminently practical and his product runs true to form. He is a man of wide and long experience of definite ideas, and a clinician with many years of teaching experience. His opinions are therefore of great weight, and his statements concise and to the point. He makes excellent use of his long years of practice in the field of pediatrics and his text gives expression to his individual views in a manner which is quite individual and characteristic.

He purposely avoids complicated laboratory methods and microscopic pathological changes, and confines his writing to the field which is indicated by his chosen title, namely, "Clinical Pediatrics."

The now rather voluminous literature of that division of medicine devoted to the infant and child is decidedly richer by the advent of this volume. The illustrations and charts are well chosen and enhance the written pages to a satisfying extent.

As a common sense and helpful contribution to the great work of rearing a better generation of citizens, Dr. Morse's book is very opportune and welcome.

WIM HENRY DONNELLY

**HAY FEVER AND ASTHMA. A Practical Handbook for Hay Fever and Asthma Patients.** By RAY M. BALYEAAT, A.M., M.D. 12mo of 198 pages with 27 illustrations. Philadelphia, F. A. Davis Company, 1926. Cloth, \$2.00.

This is a little handbook intended for the patient suffering from the above mentioned diseases and consequently it is couched in plain non-technical language.

There can be no question but that the more the general public, and especially patients afflicted with these baneful conditions, know about their origin and their

rational treatment the better will be the results of both preventive and curative methods

The relation of plants, animals and fowls to the anaphylactic group of diseases deserves broadcast dissemination so that the patient and his family circle may cooperate intelligently with the physician

The anatomy and physiology of the nose and bronchial tubes is outlined in the text, the methods of diagnosis and of treatment are simply described in such a way as not to confuse the layman with intricate technical terms  
WM HENRY DONNELLY

**HANDBOOK OF MEDICAL ELECTRICITY AND RADIOLOGY** By JAMES R RIDDELL, F R F P S 12mo of 239 pages with illustrations New York, William Wood and Company, 1926 Cloth, \$2.75

Although written for the student this book admirably meets the requirements for a brief yet thorough summary of medical electricity and radiology The simple physics of the subject is very well presented The chapters on radiology are of particular interest as likewise are those devoted to treatment with carbon dioxide snow, light and radium The latter is right up-to-date and includes the latest technique of emanation therapy The description of methods used and deductions therefrom in electrical nerve and muscle testing is particularly clear and readily understood

JEROME WEISS

**RADIOTHERAPY IN RELATION TO GENERAL MEDICINE.** By FRANCIS HERNIMAN-JOHANSON, M D 16mo of 211 pages London and New York, Oxford University Press, 1926 Cloth, \$1.75 (Oxford Medical Publications)

The general awakening and inevitable back-swing of the pendulum is again consciously and subconsciously emphasized in relation to many benign and malignant growths which for the past few decades have been assigned purely to surgery

The physics of radiation is well discussed and the value of the so-called hard and soft rays properly evaluated The brochure is intended for the general practitioner and clearly outlines the many pathological avenues through which radiation has or will probably prove to be the eventual leader to happier results

The author favors this form of treatment, tempered with surgery at times, in malignancy stressing carcinoma of the breast and cervix uteri

The Erlangen hypertensive treatments are justly condemned and broken dosage within the point of toleration favored The value of the Rays in selected thyroid states is given and many other conditions such as joint and glandular tuberculosis, numerous skin lesions, rickets, neuritis, etc., are described in relation to their respective reactions to this type of treatment

The book is well written in breezy style, interesting, and well earns a position of distinction in the select Medical library of the specialist or general practitioner

The author stresses the difference between ownership of a radiotherapeutic apparatus and proper use of same guided by intelligence and experience as follows "That a man possesses certain surgical instruments is no guarantee that he can use them to advantage, but it appears to be assumed that, in some miraculous way, X-rays either succeed or fail, without reference to any directing mind."  
MILTON G WASCH

**PRACTICAL ULTRA-VIOLET LIGHT THERAPY** A Handbook for the Use of Medical Practitioners By T CLYDE MCKENZIE, M B, Ch B and A A KING, Octavo of 108 pages, with illustrations New York, William Wood and Company, 1926 Cloth, \$2.50

An intensely interesting contribution to the science of Ultra-Violet Light Therapy A very profound study of the subject has been made by the authors, and their original theories on dosage and the action of light are advanced Of particular interest is the account of a

reliable method for determining the intensity of the ultra-violet light produced or used The methods of dosage described are in many respects unique and merit careful consideration The work as a whole is highly commendable and a valuable aid to the better understanding of an extensive and comparatively new subject  
JEROME WEISS

**THE HUMAN CEREBRO SPINAL FLUID** An Investigation of the Most Recent Advances as Reported by the Association for Research in Nervous and Mental Disease. Editorial Board, CHARLES L. DANA, M D, and others Octavo of 568 pages, with 77 illustrations New York, Paul B Hoeber, Inc., 1926 Cloth, \$10.00 (Association for Research in Nervous and Mental Disease) Volume IV (1924)

This unusual book is the result of "An Investigation of the most recent advances" in the study of the Cerebro Spinal Fluid, as reported in papers, read before the Association at the December, 1924, meeting It is the fourth volume of a series of research publications issued under the same editorial supervision

The contributors, some 38 in number, include the names of the majority of those whose work has been conspicuously prominent in this field of study It is only necessary to mention Aycock, Ayer, Christensen, Fordyce, Kolmer, Neal and Solomon to show the standing of the authors

The material presented represents the most up to date information on the subject and has heretofore been available only in the current periodicals The volume is in reality a symposium on the subject and includes the current interpretation of both the physiological and pathological aspects of the Cerebro Spinal Fluid The clinical contributions were based on over five thousand recorded examinations of the fluid from every conceivable pathologic state and include almost all known clinical conditions

This book is an indispensable reference work for all those interested in the field of investigation which the examination of the Cerebro Spinal Fluid offers in the himself with the knowledge accumulated to date on the for the general practitioner who desires to familiarize diagnosis and therapy of disease It is a useful book for the general practitioner who desires to familiarize himself with the knowledge accumulated to date on the subject The publishers are to be congratulated on the excellent appearance of the volume they have produced  
J R

**THE DUODENAL TUBE AND ITS POSSIBILITIES** By MAX EINHORN M D Second edition, revised and enlarged Octavo of 206 pages, with illustrations Philadelphia, F A. Davis Company, 1926 Cloth, \$3.00

This treatise is a valuable addition to the literature of gastro-enterology Four chapters are devoted to the history, diagnostic import and the Therapeutic Uses of the Duodenal Tube Particular attention is paid to the normal duodenal contents (duodenal juice, bile and pancreatic juice) Chapters V and VI deal with instruments, other than the tube, for the pylorus, duodenum and small intestine, thus, these chapters should not be included in this book  
B M EIS

**MEDICAL GYMNASTICS AND MASSAGE IN GENERAL PRACTICE.** By Dr J ARVEDSON Second edition Translated and edited by Mina L. Dobbie, M D 12mo of 284 pages Philadelphia, P Blakiston's Son and Company, 1926 Cloth, \$2.50

A book written for the medical gymnast, but one of great value for the physician also It describes useful gymnastic treatment for many conditions in which results ordinarily would not be sought except by other means The limit of gymnastic treatment is clearly defined in each case, and the semblance of the "cure-all" is carefully avoided There are interesting chapters devoted to the various groups of organs and parts of the body and their pathology

# OUR NEIGHBORS

## THE DOCTOR'S WIFE

The State Medical Association of Texas has a Woman's Auxiliary for whose benefit the Texas Journal of Medicine runs a department. Most physicians of New York State have wives and will be interested in the qualifications which Mrs. Rogers Cocke of Marshall, Texas, writing in the November issue of the Journal, considers necessary for the model wife of a typical doctor.

"The doctor's wife should be an expert cook, especially expert in scrambling eggs, so when the belated husband comes home hours after luncheon or dinner, he will always be assured of a wholesome meal.

"She should be a good telephone girl, much better than the average, never get numbers wrong or messages mixed.

"The doctor's wife should know all the home remedies and most of the other kind, as she is called upon to know what to do for everything from infantile colic to senile dementia.

"She should be sympathetic, kind, and tactful, and a model of patience, or she will be certain to offend.

"The doctor's wife should never express an opinion, even of her own, or she will be quoted

as having said the most impossible things about the private affairs of her husband's patients.

"It is necessary that she be a resourceful traveler, and know how to find her way around in all the cities of the United States, if she cares to go to medical conventions. This is very essential, or she may cause her doctor some annoyance.

"Mrs. M. D. must be an excellent manager. Doctors are remarkable men, most of them remarkably poor business men, so the wife must run the house, the family and the car, on the budget system, then make safe 10 per cent investments, besides.

"She should be a good nurse, an ambulance driver, a model mother, whether she has any children or not, a club woman, a genial hostess, a golfer—not necessarily a good one, that is asking too much—a bridge player, a weather prophet, a well read woman, a well dressed woman, an attentive listener, a cheerful liar, and a Christian—if possible.

"Otherwise, the requirements of a doctor's wife are few."

## THE MEDICAL RESERVE OFFICER OF THE ARMY OF THE UNITED STATES

A modern army is constructive as well as destructive, and about five per cent of its soldiers are engaged in the medical department for the promotion of health, vigor and efficiency of man power.

A large proportion of officers of the army are physicians, and they occupy positions as a powerful and as honorable as those of the infantry and artillery. Their duty is the application of medical measures under the primitive conditions of field operations, and any doctor will be a better physician because of his service in the Army.

Commissions in the Medical Reserve Corps of the United States Army are open to physicians who can pass the required physical tests. The *Journal of the Medical Association of Georgia* discusses the reserve corps as follows:

"In Atlanta we have about 40 doctors and dentists who have organized themselves into a medico-military society that meets once a month and hears lectures from competent medical officers upon the duties of the doctor in the forces. These are most interesting and such groups may readily be formed in any community. Lectures

will be supplied to them and all information as to the Department Correspondence Classes will be given helpfully. One learns not only those things in medicine and hygiene that are of value in the Army but he gets a new slant upon these very subjects in private life that are valuable in his work.

"Once a doctor has secured a commission he has the opportunity of going to Training Camps each year for his further study and gaining acquaintance with his fellow officers in the outfit to which he may have been assigned. This is not compulsory. It is a privilege that the officer will enjoy when he has learned of it. He is paid for his time as is any regular officer of like grade.

"I said that we constitute the first line of defense. I mean that so soon as an emergency has been declared by Congress and we are called to the Colors, we must begin the physical examination of the troops called at the same time. This is called processing and it is the first and most important part of mobilization after the men have been called. It depends for its success upon us and our knowledge of the peculiar things that

must be done well and quickly in order to make the Army really available

"Every doctor in the State is urged to give consideration to this matter and to proffer his services if he can do so. The older men can set a good example even if they feel that they cannot give the same amount of time to the training that the younger men can do. The younger men will find the work entertaining and the associations thus built up, pleasant. They can feel that while they are gradually acquiring a familiarity with the duties they have assumed, they are being excellent citizens and insuring an early availability of the great forces of the country if they should be needed. The late war showed that an Army cannot be raised over night, that it must consist of more than a great crowd of men. The men must be trained and know their business before they are effective. We should never find ourselves again in the predicament we were in when we had to wait a year before we knew enough to enter battle. Medical men with their wonderful influence in the communities can build up by precept and example the wholesome idea of trained military national defense, without militarism itself, better than can any other set of men.

## OLD AGE

Geriatrics is the treatment of conditions at the extreme of life opposite to that embraced in pediatrics. Old age is not a disease, but is a condition in which the person and not the disease is to be treated. Its analogy to pediatrics is close. Just as the practice of pediatrics is largely hygienic and preventive measures, so the practice of geriatrics consists in making the application of those measures which will render the patient comfortable which the natural functions of the body decline in efficiency.

The subject is considered in an editorial entitled, *De Senectute* in the November issue of *Colorado Medicine*.

"Cicero in his day attempted to palliate the burdens and infirmities of the aged by developing for them a wholesome type of thought regarding such matters. With the passing of centuries the need for such palliation has in no wise decreased. In fact, due to the diligence with which medical science has been applied, the span of life is constantly lengthening. This of course means that an increasing number escape the accidents of life to pass into the decay of the senium.

"Perhaps a revival of a philosophy similar to that Cicero imputed to the aged Cato would be a good thing. The mental attitude with which

many people approach and live the span of advanced years frequently needs correction. Unless this is done, the most skillful therapy directed toward the physical ills is likely to be of little value.

"But there are certain diseases peculiar to the aged just as truly as there are diseases peculiar to infants. There are vascular changes affecting the brain, heart, kidneys, pancreas and other organs, there are also atrophic and malignant changes of tissues with their resultant symptoms, skeletal muscular and sensory changes. These processes of degeneration and decay have a definite pathology and pathologic physiology differing markedly from the accidental and exogenous diseases of earlier years.

"The point is this, that preventive measures of medical men have created new problems in therapy. Special thought is, therefore, desirable in the organization of therapeutic measures peculiarly adapted to the infirmities of the aged. Certainly much can be done to lessen the load of senile changes. Probably there exists no good reason for the creation of a distinct specialty of geriatrics, but there is a growing need for the development of the art of medical practice effective in alleviating the physical and mental handicaps of senile origin."

### CONTRASTING OFFICES

The editorial comments of the December issue of the Journal of the Michigan State Medical Society contains an article entitled "Thoughts while visiting about," which reads:

"Doctor's reception room revealing rare specimens of antique furniture—broken. Table littered with year old, dirty magazines, dust in corners. Doctor's desk a mass of pills, bottles, circulars, cigar stub, unopened journals and a dirty

blotter. Bottles of urine in medicine closet. Soiled dressing and cotton in open waste basket. Speculums and female treatment instruments on window sill. Dirty pillow on examining table.

"This in contrast with the most modern, well-kept, neatly furnished offices of another doctor just across the street. A group of rooms labeled 'Clinic.' A registration desk where patients' civic data is obtained, as also fees. A lot of record cards supposedly containing histories but the recorder could never qualify in a history department—it's an art. Everybody from colored maid to chief robed in white—gowns are great concealors of physical anomalies. Odor of ozone from sputtering vibrators, diathermy and 'lights' at so much per treatment and rare is the case that doesn't need some form of light or electric treatment—if properly farmed. Absence of array of cathartic pills—evidently they are *passé*—the thought persists from the old days that a good bowel movement often still achieves results. A suggestion for Clinics in a Dietary department to give much needed instructions as to how and what to eat.

"Oh, well, sometimes we hope a new lay organization will be formed devoting its efforts to reforming doctor's reception and consultation rooms. In the meantime you might call in the local painter, furniture and carpet men and spruce up your old dump. Office girls chewing gum, answering phone loud enough so all in hearing may know that the doctor is still at the hospital operating, or is in Athens in consultation, or is called to see Oudin. A manual on 'office girl's' imparting advice on style, technic and effective methods should be forthcoming from a facile pen. A substitute picture for that of 'The Doctor' should displace this time worn wall adornment of pristine glory. So, too, the advertising clock stating 'The Doctor Is Out, Will Return at—'

The "Motion Picture Course in Proctology" offers a unique opportunity for

## MORTALITY IN INDIA FROM WILD ANIMALS

Primitive man doubtless found his greatest source of terror to be wild animals—the bears and tigers, which infested his cave dwellings, the mastodons, which devastated his clearings, the snakes which seized his children, and the crocodiles which awaited him in the water. All these are still a deadly menace in some parts of India, as is shown by the following extract from the London letter in the November 20th issue of the *Journal of the American Medical Association*:

"That the toll of human life that wild animals and venomous snakes take in India every year is decreasing is shown by the annual returns for 1925, which have now been received from local governments and administrations:

"Tigers are again responsible for the largest number of deaths. The total number of persons returned as killed by wild animals in British India during the year is 1,974, as against 2,587 in the previous year and 3,605 in 1923. Tigers were responsible for 974 of these deaths, leopards for 191, wolves for 265, bears for 82, elephants for 78 and hyenas for 6.

"Madras returned the highest number of deaths caused by tigers, the Central Provinces and Berar the highest number caused by leopards, the United Provinces by wolves, Bihar and Orissa by bears, and Assam by elephants. Of 388 deaths caused by other animals, 73 are assigned to wild pigs and 98 to crocodiles and alligators.

"The highest number of deaths caused by all wild animals occurred in Madras (464), Bihar and Orissa, the United Provinces and the Central Provinces and Berar coming next in order.

"The mortality attributable to elephants showed a marked increase in the provinces where the animals are mostly found. There has been a noticeable decrease in deaths caused by all other animals, except bears, in almost all the provinces.

"Deaths from snake bite fell from 19,867 to 19,308. Decreases occurred in Madras, the United Provinces, the Punjab, Burma, Bihar and Orissa, the Central Provinces and Berar and Assam, but Bombay and Bengal have reported slight increases during the year under review.

"Wild animals numbering 21,605 were reported to have been destroyed, of which 1,609 were tigers, 4,660 leopards, 2,485 bears and 2,361 wolves. A sum of 155,667 rupees was paid in rewards, against 169,765 rupees in the previous year. The number of snakes destroyed in India proper decreased from 47,106 to 41,004, and rewards paid for their destruction were 1,579 rupees, as against 1,403 rupees in the previous year."

## THE SMALLPOX MENACE

The London letter in the November issue of the *American Medical Association* comments on smallpox in England and says:

### The Smallpox Menace

"In a letter to the press, Sir Leonard Rogers, an authority on tropical medicine, comments on the increase of smallpox in the North of England and the recent cases in London, which should awake the country to the fool's paradise in which we are living in consequence of neglect of vaccination. The following official figures show the rapid increase of the disease: 1921, 315 cases, 1922, 973, 1923, 2,485, 1924, 3,765, 1925, 5,354. The very low mortality from the disease recently in this and other countries has lulled the public into a false sense of security. The influence of such a dry season as the present in favoring smallpox epidemics was pointed out by Mr. Baldwin Latham in 1890 and has recently been confirmed in India, so everything seems ripe for the nemesis of neglected vaccination, ever since in 1907 parliament relaxed the powers of compulsory vaccination, and since then so further weakened them by administrative action as to make it more troublesome to submit infants to vaccination than to avoid it. Smallpox in a poorly vaccinated community, such as that of Great Britain today, is mainly a disease of childhood."

## A New Source of Fresh Cod Liver Supply

*The beam trawler is one of the types of fishing boats that sail from our Atlantic ports*

To supply the constantly increasing demand for Patch's Flavored Cod Liver Oil it has been necessary for us to greatly increase our liver supply by installing many new plants along the Atlantic coast during the past year.

We have also developed a type of cooker which is being successfully operated on the large steam trawlers while they are far out at sea.

As soon as the nets are hauled in the fish are immediately cleaned. The fresh livers are taken by our men who ship with the crew directly to the cooker where the oil is extracted at once.

The excellent crude oil thus produced right at the source of the fresh liver supply is taken to our main plant at Gloucester Mass. Here it is chilled to remove the stearin.

Only by giving close attention to the matter of fresh liver supply can we maintain the high quality of PATCH'S FLAVORED COD LIVER OIL, a sample of which will be mailed to you if you will send us the coupon below.

Taste it! You'll be surprised!!

## THE WOMEN'S AUXILIARY IN MISSOURI

The December issue of the Journal of the Missouri State Medical Association contains the minutes of the meetings of the Women's Auxiliary of three counties of Missouri.

The Auxiliary of Gentry County held a joint meeting with the County Medical Society on October 7, and discussed ways of increasing the circulation of *Hygeia*. Plans were discussed to send *Hygeia* to the teachers of the public schools of the county.

The meeting adopted the "Seymour" plan of disease prevention advocated by Dr. M. M. Seymour of Saskatchewan. The plan consists in intensively educating the public regarding a single disease at a time. The subject in September and October will be diphtheria, in November and December, smallpox, and in January and February, typhoid fever.

The meeting also discussed the popular distribution of the preventive literature prepared by the Metropolitan Life Insurance Company.

The Holt County Auxiliary was organized on November 5th, and plans for popular medical education were formed in cooperation with the county nurse.

The St. Louis Medical Society Auxiliary met on November 3 in the new building of the St. Louis Medical Society for a social evening. Plans were discussed for raising funds for the improvement of the building.

## THE WOMEN'S AUXILIARY IN VIRGINIA

The Woman's Auxiliary Medical Society of Virginia held its annual meeting on October 13 in Norfolk, according to the December issue of the Virginia Medical Monthly. The principal speaker was Dr. Olin West, Secretary of the American Medical Association, who urged the Auxiliary to stand behind the Health Department and especially to see that each doctor promptly reported each birth and death. He said that the Auxiliary would find its best field of usefulness in rural districts, for in them there is a lack of other organizations.

Mr. Frantz Naylor, President of the Women's Club of Norfolk, gave an outline of the public health work of the Auxiliary in the Club and said that the auxiliary and club had already carried on many activities along the lines suggested by Dr. West.

Standing Committees were appointed on Education and Publicity, Hygeia, Legislation, Organization and Parliamentary Practices.

## MEDICAL ASPECTS OF THE TREATMENT OF ABSCESS OF THE LUNG\*

By JAMES ALEXANDER MILLER, A.M, M.D, NEW YORK, N Y

THE treatment of acute pulmonary abscess is primarily medical. After a period involving a good deal of experimentation, surgeons and internists alike have come to agree that surgical operation during the acute stages of abscess of the lungs is a very hazardous procedure. Consequently, when cases of abscess of the lung are seen early in the disease they belong in the domain of internal medicine. This does not mean that abscess of the lung may not be a surgical condition. It often is, and the ideal procedure is to have any case followed along coincidentally by both surgeon and physician, in order that the progress of the condition may be watched carefully from both points of view and the indications for change of treatment, which may involve a shift of responsibility from the internist to the surgeon, may be recognized and the best opportunity for recovery thus afforded the patient.

It is interesting to note that the literature contains reference to several methods of medical treatment, for all of which are claimed excellent results. On the other hand, not a few surgeons who have written on this subject have felt that the responsibility was primarily a surgical one and it is only until late years that any general recognition of the primary responsibility of the physician has prevailed.

The experience upon which this present presentation of the treatment of abscess of the lung is based has been obtained over a period of five years in close cooperation between Dr Adrian V S Lambert and me, (1) during which time more than one hundred cases of abscess of the lung have been jointly studied. As a result of this experience a rationale of treatment has been developed which is partly medical and partly surgical and which we believe has certain advantages over the special forms of treatment which have hitherto been advocated.

The technique which we have jointly worked out is best termed a "system of management" rather than a method of treatment, for we are impressed by the variability of response of these

cases to any given therapeutic method, and by the frequent necessity of modifying or combining various methods in order to obtain best results in any given case. We have found it futile to accept any one method as generally applicable but in the study of our cases we have been able to employ all of the usually recognized methods to more or less advantage, and we have therefore no new method to suggest but, rather, a method of approach which has left us free to apply any or all known methods according to the indications presented. It is the study of the indications which we would particularly emphasize.

All cases of abscess of the lung when first presented for treatment we regard as medical cases and they are put under strictly medical supervision for careful study involving physical and X-ray examinations, careful measurement of the amount of the sputum, the character of the cough which produces it, the bacteriology of the sputum, the behavior of the temperature, and particularly the progress of all of these factors during at least one week of careful observation.

### BED REST

The primary and basic treatment is absolute bed rest combined with postural drainage. It is only recently that we have come to what we now believe is a proper appreciation of the value of prolonged bed rest in the treatment of acute lung abscess. We were influenced considerably by Pritchard's (2) valuable contribution to this aspect of the subject and have come to agree very heartily with his conclusion, and we feel that this part of the treatment has been too much neglected, particularly after the patient may become nearly or entirely afebrile. During the febrile period bed rest is obviously indicated and probably universally employed. In a considerable number of cases the fever subsides more or less promptly even when drainage through a bronchus is inadequate, and it is quite common to note a consistently normal temperature without a correspondingly satisfactory decrease in cough and expectoration or improvement in the

\* Read at the Annual Meeting of the Medical Society of the State of New York, at New York, March 31, 1926.

character or extent of the lesion as shown by X-ray. Under such circumstances the general condition of the patient is naturally better and often confinement to bed becomes irksome, but we believe that persistence in bed rest until the cough, expectoration and X-ray findings, as well as the temperature, all indicate the clearing up of the necrotic process in the lung is most important and will materially assist the postural drainage treatment which is combined with it in obtaining a so-called medical cure. Moreover, we believe that rest plays a valuable role for many weeks after all symptoms have been absent, especially if the X-ray densities have not absolutely cleared up, for in such cases relapse may occur even many weeks after the symptoms have disappeared, and we have had reason on several occasions to regret a premature discharge from hospital supervision or return to normal activities of life.

We therefore advise a prolonged period of rest for weeks or even months of an after-cure very similar to that employed in the management of a partially arrested case of pulmonary tuberculosis. In this after-cure hard physical work or violent exercise are excluded and rest in a recumbent position is required for considerable periods of each day, these being gradually diminished and increased activity allowed until a normal degree of active life is obtained and a permanent cure is effected, but rest alone will not be sufficient in a considerable number of cases.

#### POSTURAL DRAINAGE

Cough with the expectoration of pus occurs in all cases of lung abscess in which there is a communication with a bronchus. Complete drainage of the abscess may result in this manner and a spontaneous cure thus effected in a limited number of cases. As a rule, the cough, while producing the expectoration of foul pus in large quantities, only succeeds in eliminating the amount which constantly wells up into the bronchi, leaving the abscess cavity itself still completely or partially filled with pus, with consequent increasing necrosis and collateral inflammatory reaction in the lung itself. Certain positions of the body will very frequently aid in the more complete emptying of the cavity by the cough and thus the proportion of cases cured by this natural method of drainage may be materially increased. Patients will themselves frequently note that certain positions increase the amount and ease of expectoration and these observations are often valuable guides to postural treatment.

In general, we invert the patient completely with the head hanging straight down to the floor bending at the waist over the edge of a bed. A twist of the body so as to bring the affected side to a higher level than the opposite one is often desirable. Sometimes lying on the back with the head down, with the body held in position

by the bend of the knees is more effective. This can be accomplished by the reverse use of the break of a Gatch bed, or by lying over a stiff chair inverted and placed upon a flat bed. Sometimes the best results are obtained by positions which have no logical explanation as far as the location of the abscess is concerned, and we have been interested to note that upper lobe abscesses are quite as apt to drain by the inverted posture as are those situated in the lower lobes. In any event, considerable time must be spent in patient experimentation with each case to discover the best position for that particular patient.

After this has been determined, this posture is prescribed at regular intervals, usually every three or four hours at first, and is maintained for periods varying from five to fifteen or twenty minutes. The discomfort felt in the head from the inverted position quickly disappears and patients rarely complain of it after the first day or two. An observant patient soon learns from his own sensations when he needs drainage and the interval and duration of each treatment is modified accordingly.

The effect of this treatment is very striking when successful. The more complete emptying of the cavity gives a complete cessation of cough for hours at a time, allowing a very gratifying relief from the constant and harassing paroxysms which so often mark this disease. The amount of expectoration which is carefully measured and noted for each twenty-four hours, at first very materially increases and then in a few days gradually diminishes until it may entirely disappear in a week or ten days. The fever subsides and the patient is transformed from a miserable and acutely ill person to a comfortable convalescent. Many times these desirable results are only partially obtained and in still other cases no appreciable result in amelioration of symptoms is noticeable. In such cases after adequate trial it is necessary to supplement this treatment by one or the other of the other methods to be later considered.

We are accustomed to persist in this treatment for at least three or four weeks before discarding it, because not infrequently good drainage may be established quite suddenly in cases which have shown no results during the first weeks. In the evaluation of this, as well as all other methods of treatment, the comparative Roentgen-ray films are the best single guide.

This combination of rest and postural drainage constitutes, therefore, our basic method of treatment, to be first used in practically all cases, and the result obtained affords a point of approach to the consideration of additional methods which may be necessary. In our experience, about twenty per cent. of all cases are cured by these methods alone.

### THE ADMINISTRATION OF SALVARSAN

It is pretty generally recognized that any chronic inflammatory condition in the lung, whether it be tuberculosis or a chronic empyema or pulmonary abscess, when occurring in a syphilitic patient is favorably affected by the specific treatment directed toward the underlying syphilis, and consequently in pulmonary abscess it should be an invariable rule to have a Wassermann test, which, should it be positive, would be a direct indication for the use of salvarsan immediately, even during the febrile period.

More than this, however, it is generally recognized that many of the secondary bacterial invaders in pulmonary abscess, which are responsible for the characteristically foul odor of the expectoration in this disease, are the anaerobic organisms, many of which are spirochetes. It is still somewhat of an open question as to how far these anaerobic micro-organisms are merely secondary invaders and how far they may play a direct etiological rôle in the formation of the disease. It is our own impression that the latter not infrequently is the case, but we have not yet obtained any direct evidence on this point. But whether the spirochetes are primarily the cause of the abscess or whether they are simply secondarily the cause of the production of the foul necrotic pus in an abscess caused primarily by a pyogenic micro-organism, it appears to be a fact that the use of salvarsan or neo-salvarsan not infrequently has a very favorable effect upon the symptoms of the disease. It does not appear proven that such cases should be classified as cases of spirochetosis, but inasmuch as the spirochetes play an important rôle in the development of the pathological process, any form of treatment which will eliminate them from the process is helpful and the arsenical preparations appear to offer us this opportunity. As a result, in cases where rest and posture alone do not clear up the condition, very frequently the use of neo-salvarsan in comparatively small doses beginning with three decigrams and repeating at five to seven-day intervals with increasing doses up to a maximum of nine decigrams, will very materially affect the condition of the patient favorably by clearing up the amount of cough and foul expectoration. This method of treatment is perhaps even more important in the cases which tend to become chronic where the anaerobes in the expectoration appear to be largely of the spirochetal variety.

We have no definite figures to present as to the precise result of this method of treatment alone, inasmuch as it is combined with other methods, but we are most favorably impressed with its value in a considerable number of cases.

### BRONCHOSCOPIC TREATMENT

Our earlier experience led us to doubt the general applicability of the bronchoscope in the

treatment of lung abscess. We were also impressed by the fact that some fatalities occurred and that very frequently it was a most distressing ordeal for the patient.

We have considerably modified our previous point of view in the experience which we have had through the close cooperation of Dr. Kernan in the study of many of our cases. While we cannot share the enthusiasm of some who consider the use of the bronchoscope as the most important method to be first considered in these cases, we do feel that in many it may facilitate drainage when it is not promptly established by the rest and postural plan.

We believe, however, that the possible dangers and discomforts of this method are eliminated only if it is in the hands of a very skillful operator of large experience and mature judgment. We feel that the occasional bronchoscopist should not attempt the treatment of lung abscess.

That this method in skilled hands is useful and not dangerous in properly selected cases is evidenced by the considerable experience now reported by such bronchoscopists as Chevalier Jackson (3), Lynah (4), Carmody (5), Yankauer (6), Kernan and others, by the testimony of such thoracic surgeons as Lilienthal and Willy Meyer (7) and by the experience of internists such as McCrae and Funk (8). They emphasize the importance of early treatment in acute cases and report occasional very prompt cures, often great improvement, and in chronic cases amelioration of symptoms with occasional cure.

This has also been our experience but we emphasize the importance of rest and posture as basically important and the use of the bronchoscope, which can only be employed at about weekly intervals, as a most valuable adjunct to this treatment in many cases by helping to establish more prompt and direct drainage.

It is our experience that it is the passage of the tube, combined with suction, which is valuable, and that lavage and the introduction of such medicaments as antiseptics, local stimulants, bismuth and the like, have no value and may do harm. We do not favor bronchoscopy in abscesses situated near the periphery of the lung, it is contraindicated in those not communicating with a bronchus, and is less apt to be successful in lesions situated fairly high up in the upper lobes. It is most useful in abscesses situated near the main bronchi, especially those in the lower lobe, but it is to be noted that it is just in this class of cases that rest and posture alone are most apt to succeed.

For the diagnosis and cure of abscess due to foreign body inhalation, bronchoscopy is the method of treatment, and for the diagnosis of new growth in the lung simulating a true abscess it is invaluable. It is also of value in accurately localizing the lesion in cases which come to radical surgical operation. We advise this method, therefore, in acute abscesses which do not

promptly drain with posture, when the location is not near the periphery, in chronic cases for the amelioration of distressing cough and expectoration and for the diagnosis and localization of the lesion

In about ten per cent of our cured cases bronchoscopy has played an important rôle.

#### ARTIFICIAL PNEUMOTHORAX

The success of collapse therapy in certain cases of pulmonary tuberculosis very naturally has led to its consideration as a possible useful procedure in other pulmonary conditions and among them lung abscess

We have employed this method in some cases, but tentatively, in order to have actual experience as a basis of judgment, rather than with great confidence in it as a rational procedure. The reason for this somewhat experimental method of approach is found in our conception of the radically different objects to be attained in pulmonary tuberculosis as opposed to abscess of the lung. In tuberculosis, rest and immobilization of the lung appears to us to be the prime consideration and for this often partial pneumothorax without any actual compression of the lung is adequate

In abscess, drainage is the desired object, and by artificial pneumothorax this can only be facilitated by pressure properly applied upon the right point and in the right direction. We do not feel that this can be accurately gauged in artificial pneumothorax. Moreover, it sometimes happens that the air introduced works around into the pleural space near the mediastinum and may actually cut off drainage already partially established, resulting in an exacerbation rather than a relief of symptoms. This has been our experience in some cases and has been reported also by others. We also feel that the expulsive action of the cough, which is, after all, the one most important factor in lung drainage, may be hampered in a lung partially immobilized by a pneumothorax

Our most serious objection, however, is the very real danger that the pleura may be ruptured when this method is employed in abscesses, with a resulting acute septic empyema necessitating immediate operation and under circumstances which render the danger to life exceedingly great. We have had a few such experiences and reports of similar cases occur rather frequently in the literature

Tewkesbury (9) is perhaps the warmest advocate of artificial pneumothorax in the treatment of lung abscess and he reports very considerable success. He advocates its use as soon as the diagnosis is established, the earlier the better, if possible before any pleural adhesions are formed. He does not, however, state that it is not to be used in more chronic cases. Others have also reported successful results but usually

in very small series of cases and among these are also some of the unfortunate ruptured cases above noted, and we cannot escape the impression that many cases have been treated without careful study of the other possible methods of treatment and without due regard to the dangers that may be involved

Upon the whole, therefore, we believe that this procedure carries with it too great a risk to warrant its employment as a routine procedure in the treatment of lung abscess, at the same time realizing that with a fortunate combination of circumstances, especially in lesions situated near the hilum, brilliant results, as in one of our own cases, may be obtained by its use.

We have consequently employed artificial pneumothorax in only ten cases out of the one hundred which we recently gathered together for study and in one of these prompt recovery ensued. In the others it seemed to have little or no effect

In general, therefore, we believe that the medical treatment of abscess of the lung is primarily bed rest and postural drainage, combined in certain types of cases already described with the intravenous use of neo-salvarsan, and in certain other cases, particularly where the abscess is near the hilum and which do not promptly improve with the above methods, by the additional use of bronchoscopy

Taking it all in all, in our results about fifty per cent of all cases of abscess of the lung are cured by these conservative measures alone

#### INDICATIONS FOR SURGICAL INTERVENTION

While, as above stated, we believe that surgical intervention is most unwise and dangerous in the acute stage of pulmonary abscess, on the other hand it is equally unfortunate to delay operation after it has become evident that the above described medical procedures are not leading to satisfactory results

In general, if a case of acute or subacute abscess has not made very considerable progress toward cure in a month or six weeks from the time that medical treatment is instituted, it is not likely that absolute cure will result from medical treatment alone, and it is in these cases that operation is indicated. On the other hand, however, in a very large majority of these cases the medical treatment has succeeded to the extent of allowing the acute process to subside and the pathological process to become more localized into a pure necrotic area with very much less of the hyperemic zone of empyema surrounding it than originally was present. It is during this stage that operation is much less dangerous and consequently the medical treatment may be looked upon in such cases as a preparatory one to successful surgical treatment

In our experience about fifty per cent of the cases eventually come to operation but because

of this preliminary medical care the surgical mortality has been materially reduced, in our recent experience being not greater than ten per cent, when previously the surgical mortality as reported in the literature ranged anywhere from thirty to seventy per cent in cases operated upon

#### SUMMARY AND CONCLUSION

1 The successful treatment of cases of abscess of the lung is materially aided by their joint management by internist and surgeon, with the close cooperation of a skilled bronchoscopist

2 A systematic plan of prolonged rest, combined with postural drainage, is the basic method of treatment. The intravenous use of neo-salvarsan is frequently of added benefit

3 Bronchoscopy is of real value as an aid to drainage in certain cases. Artificial pneumothorax has a very limited field of usefulness

4 Approximately fifty per cent of all cases will eventually need radical surgical treatment. Correct judgment of the indications for operation

is the crucial element in successful treatment. In general, it is based upon the avoidance of surgical intervention during the acute phases of the disease but without delaying too long and thus allowing the case to drift into the chronic stage.

### PULMONARY ABSCESS AND ITS TREATMENT FROM THE SURGICAL STANDPOINT\*

By ADRIAN V S LAMBERT, M.D., NEW YORK, N Y

THE whole subject of pulmonary suppuration is extremely complicated and there exists a considerable degree of confusion because of the failure to recognize that the term may refer to very different pathological processes. When we attack by surgery any particular case our success depends on having a clear conception of exactly what it is we are attempting to relieve. Many of the failures are directly attributable to some misconception of the lesion present in a particular case.

In discussing the surgical treatment of lung abscess it is well to consider in some detail what is meant by lung abscess in order to avoid in our discussion a confusion of ideas due to any misunderstanding by terms.

Many patients who have a profuse foul smelling sputum with constant distressing cough do not have a lung abscess, but are suffering from some other form of suppurative disease of the lungs.

We will confine the term lung abscess to a particular type of pulmonary infection, a suppurative pneumonitis, the characteristic lesion of which is a cellulitis of the parenchyma of the lung with a breaking down of the walls of the alveoli and the formation of a cavity filled with the products of this necrosis which from time to time may be coughed up dependent on whether there exists a

communication with the larger branches of the bronchial tree. This cellulitis of the lung parenchyma gives rise also to an oedematous swelling of alveolar walls with an infiltration by leucocytes and an exudation of serum into the alveolar spaces in a zone of varying extent about the central necrotic focus. The alveoli in the immediate neighborhood of the central focus are usually collapsed with their walls in contact and it is this zone of collapsed alveoli which is frequently spoken of as the wall of the abscess. The exact nature of this wall depends largely on the duration of the abscess, for after a prolonged period of suppuration these collapsed alveoli lose their respiratory epithelium and become connective tissue strands, in whose interstices many bacteria may be present. Such a group of alveoli are not capable of re-aeration and account for the shadows present on X-ray examination long after the symptoms of the disease have disappeared and the patients are apparently cured. The bacteria may remain in this tissue a long time and account for the relapses of the disease so frequently seen in patients who insist on too much activity too soon after an apparent cure.

Such a focus when first seen is usually considered and spoken of as pneumonia and not until a free communication with a larger bronchus has become established is the correct diagnosis arrived at.

In confining our attention to this particular

\* Read at the Annual Meeting of the Medical Society of the State of New York at New York, N Y, March 31, 1926

group of pulmonary suppurations we have purposely ignored those cases due to infection by the tubercle bacillus, those dependent on the presence of dilated bronchi with thickened infected walls, bronchiectasis, those due to the presence of foreign bodies, those resulting from neoplastic growths, and the cases of extensive pulmonary gangrene

Each one of these latter groups presents a particular problem and this fact but emphasizes the extreme importance of a correct and most exact diagnosis in all cases of pulmonary suppuration

To go into the minute details of the differential diagnosis between these several conditions would, I fear, lead me too far afield in the limited time at my disposal, but I wish to emphasize the great importance which bronchoscopy plays in the problem, in neoplasms, foreign bodies, and the location of the abscess it is an invaluable aid. I do not consider that the procedure is devoid of all risk, but in expert hands this may be reduced to a minimum. Its value, however, may be so great that it is well worth while to face that risk for the sake of the important information which may be gained, in addition to the possibility of effecting a cure by that means alone

The crux of the successful treatment of lung abscess may be summed up by the one word drainage, and in the management of any given case the problem is to effect adequate drainage

It might be well at this time to emphasize the fact that in our series about 50% of all cases recovered completely under the more conservative forms of treatment without operation

By the term surgical treatment we all have in mind the establishment of drainage through an opening in the chest wall and for its success several things are important

- 1 Time at which to operate
- 2 Exact location of abscess
- 3 Technical surgical details

#### TIME AT WHICH TO OPERATE

The ideal time at which to drain a lung abscess through the chest wall is when the zone of exudative inflammation has been reduced to a minimum and the central cavity is surrounded by a series of collapsed vesicles, representing a more or less discrete wall. This condition may best be attained by treating the patients by conservative methods of postural drainage aided by bronchoscopy in suitable cases and by absolute bed rest. This stage may best be judged by frequent X-ray examinations and by following closely the character and amount of the daily sputum. It is a dangerous thing to treat a lung abscess by open drainage while there is an extensive zone of exudation about the central suppurating focus, because as soon as we establish a free opening through the abscess with a communicating bronchus we diminish or even abolish the expulsive effect of coughing on this zone of exudation, in other

words we prevent the drainage in the vesicles of this zone and the process is liable to extend widely throughout other portions of the lobe involved and often extends to other portions of the lungs, and there results a wide-spread septic pneumonia which may rapidly prove fatal

#### EXACT LOCATION OF ABSCESS

Before undertaking the operative drainage of an abscess it is most important to accurately establish its exact location and if possible the point where it is nearest to the chest wall. Physical signs are often quite misleading and we have found that X-ray plates taken in two planes and the fleuroscopic mapping of the abscess on the chest wall are the best means at our disposal. The bronchoscope may also give us valuable information

It is not sufficient to simply locate the lobe in which the abscess may lie but we should if possible ascertain whether it is anterior, posterior, lateral or central. I might add that abscesses situated near the hilus are the most difficult to drain by incision but fortunately they usually recover without operation

#### ANESTHESIA

In the choice of an anesthetic we have employed both local anesthesia and general. Nitrous oxide gas with oxygen or ethylene with oxygen are the best general anesthetics. We never employ ether as being contraindicated on account of its irritating qualities. There are advantages in both the local and general anesthetics but of late we have used general anesthesia because it has the advantage that should collapse of the lung occur because of the lack of adhesion the lung may be blown up and thus diminish the danger from a possible shift of the mediastinum. We have had no accidents from the inhalation of sputum into the other lung during general anesthesia

On opening the chest by the resection of a liberal portion of one or more ribs the presence or absence of adhesions should be ascertained. If there are none present it is wise to pack the wound with gauze and wait for three or four days to a week until the two layers of pleura adhere. There is danger of establishing a severe type of empyema if the abscess is opened when a pneumothorax is established. The smallest opening may prove disastrous in this respect as happened recently to me although the opening was minute in size, was packed off with gauze and apparently closed

I feel that the use of the aspirating needle on the unopened chest in order to establish the diagnosis is an unjustifiable procedure for the same reason, namely the danger of establishing an empyema. After the pleura is exposed and the presence of adhesions established the needle may be an aid in locating more exactly the site of the abscess. It is not, however, without danger as was demonstrated on a case which died suddenly on

the introduction of the needle as the first step in the second stage of a two-stage operation. These sudden pleural deaths I feel have not been satisfactorily explained but do occur from time to time. As a rule I avoid needling the lung.

I have opened the abscess with a scalpel and have not used the cautery, and up to the present have not encountered any severe hemorrhage from the procedure. After opening the abscess it should be explored with the finger and the opening enlarged so that the drainage may be placed at its most dependent portion.

As a drain I use a collapsed cigarette drain covering without any contained gauze and place a rubber tube of large calibre and of soft texture just inside of the abscess wall leading the cigarette covering to the surface through its lumen. I feel that the character of this rubber tube is important and should not be the stiff, hard piece of hose so frequently found in hospitals, with about as much elasticity as an ordinary iron gas pipe. The walls of the tube should be relatively thin as compared to the size of its lumen. I employ gauze packing only to control severe hemorrhage and find that I use it increasingly seldom.

The incisions of the superficial layers of the chest wall are then packed with iodoform gauze

about the tube. This acts as an excellent protective against infection.

The patient is kept on his operated side until he has completely established his respiratory equilibrium and emptied his bronchial tree of contained secretion.

Drainage of such an abscess must be maintained over a long period, several months or until such time as the X-ray shows a complete clearing of the surrounding lung and a granulating tract is established. The fear of establishing a permanent bronchial fistula in such cases is, I think, exaggerated and the difficulty in most cases is to maintain a free opening as there is a great tendency for the tract to close prematurely.

The case should be kept in bed until he is free of all symptoms and there is no odor to the discharge.

I should like to emphasize again before closing the importance of the treatment preliminary to operation and to again draw attention to the fact that many cases of abscess will recover without operation if placed on a proper regimen, that it is dangerous to operate during the acute stage and that a precise localization of the site of the abscess is necessary for a successful operative attack.

## RESULTS OF THE LONG-CONTINUED USE OF INSULIN IN DIABETES\*

By JOHN R. WILLIAMS, M.D., ROCHESTER, N. Y.

Highland Hospital, Rochester, New York

1 Before one can measure the value of a remedy in the treatment of diabetes, there must be learned what can be gained by the proper application of diet, rest, and regulation of personal hygiene. Dietary control alone produces remarkable results, but more or less temporary and variable in character. In a consideration of this point in connection with the introduction of insulin, 100 cases were carefully studied. For most patients on diet alone it required from two to four weeks to gain the maximum food tolerance with a normal blood sugar. Most of the patients were able to gain in glucose utilization from 25 to 100 grams. In about half the cases this gain would remain stationary or slightly increase for six months, while at the end of one year the loss of tolerance would begin to be noticeable and retrenchment would be necessary. In nearly half the cases after one year there was a loss of from 25 to 50 per cent. This preliminary ability to gain and the subsequent loss in food tolerance on diet alone must be thoroughly considered in an evaluation of insulin.

In order to determine the added aid of insulin to diabetics who had dietary therapeutics, I have selected from our series 28 cases who had been dieted thoroughly and who had been under observation sufficiently long to determine the lim-

itations and beneficial possibilities of this procedure. When insulin became available they were all put on this treatment. Insulin therapy began with some of this series in May, 1922 nearly four years ago. They are therefore as long treated with insulin as any group of cases in the world.

2 FOOD TOLERANCE.—At the end of treatment—preinsulin period, 21 of the 28 cases had lost in food tolerance from 200 to 1000 calories, 7 were barely maintaining a low fixed tolerance. Of the same group four years after insulin, 27 had gained in food tolerance and were on diets above the normal maintenance requirement.

3 BODY WEIGHT AND GROWTH.—In the preinsulin period, 15 of 28 cases had lost from 5 to 30 pounds each, or a total of 218 pounds. Eight were maintaining a constant weight and 5 cases had gained from 4 to 14 pounds, or 40 pounds. Seventeen were below and 9 above their standard weight. Since insulin 24 of the cases have gained 407 pounds. Two cases have lost 22 pounds. Thirteen of these cases are still below their ideal weight, 4 are normal and 11 above standard weight.

Before insulin, increase in body stature in a series of 28 children was slight or negligible. Seven preinsulin children, who made no growth progress before, have rapidly grown and developed since.

\* Read at the Meeting of the Medical Society of the State of New York, at New York, March 30, 1926.

**4 ECONOMIC EFFICIENCY**—The physical efficiency of these 28 cases before insulin was as follows: 12 were able to do some or all of their usual duties, 6 cases were about but unable to work, 11 were bad cases and helpless. Today 21 are able to do full duty and 7 part duty. None are now helpless. Formerly the majority of all moderately severe or severe diabetics had to gradually abandon work. Now practically all of them are able to continue at full or nearly full time work, unless prevented by complications.

**5 FATE OF LARGE GROUPS BEFORE AND SINCE INSULIN**—In a five-year period prior to the discovery of insulin, we studied carefully the fate of 304 cases of all ages, treated by the Allen method. Two hundred one or 66 per cent were living and 103 or 34 per cent had died.

In the four-year period in which we have used insulin, we have studied 478 cases of all ages. Four hundred four or 85 per cent are living and 74 patients or 15 per cent are dead.

**5 CAUSES OF DEATH**—Before the advent of insulin under the Allen method, over a five-year period, out of 103 fatal cases 71 apparently died of diabetes, the remaining 32 dying of complications.

In the four-year insulin period, 74 cases have ended fatally, of these 16 have been due to diabetes, and 58 deaths to complications. In 7 of the diabetic deaths, patients were only treated for a few hours.

**6 DURATION OF LIFE**—Before insulin a child under 10 years with diabetes rarely lived two years. Between the ages of 10 to 20, death occurred in from two to four years, and from the ages of 20 to 30 in from four to six years. After 30 years the period extended from five to 15 years. Since insulin there have been few deaths due to diabetes alone where properly treated. The tenure of life has been indefinitely extended.

**7 INSULIN DOSAGE**—While the great majority of newly treated cases are able to either diminish the dose or discontinue insulin after using it for a few months, in my series of 28 pre-insulin cases who had attained a fixed or were in a state of declining food tolerance, none have been able to discontinue it. Only 2 cases have been able to reduce the dose, 8 cases have been able to get along without increasing it in spite of substantial gains in body weight, while 18 have had to increase the dose although body weight gains account for a part of the increase. In two children there has been a striking increase in insulin requirement, from 80 to 210 units daily in one child, and from 20 to 190 in another child. Both children have gained greatly in growth and weight.

**8 COMA**—Insulin apparently does not lose its potency in the relapses which follow indiscretions in diet, or from the failure to use it properly. I have had 3 cases in which profound coma

has occurred eleven times, promptly relieved and returned to their metabolic status previous to the relapse. Repeated attacks of diabetic coma do not appear to have appreciably hurt these patients.

**9 EFFECT ON SKIN OF PERSISTENT NEEDLE PUNCTURES**—It was early predicted that the continuous use of the hypodermic needle would destroy the skin so that ultimately it would not be possible to administer insulin by the subcutaneous method. Experience does not justify the fear. One of my cases has had upwards of 4,200 injections about the buttocks and thighs. Treatment in this case was begun in May, 1922, when insulin was impure and caused several large and very severe abscesses. Nevertheless, this patient's skin today is in good condition and shows no ill effects from the repeated needle punctures. Eight cases under my care in a little over 4 years have had upwards of 23,000 needle punctures with no apparent ill effects.

**10 OVER DOSAGE—HYPOGLYCEMIC SHOCK**—Patients are commonly receiving over dosage of insulin. I have seen no bad effects from this except in one case where a patient at home lost his life because proper relief was not afforded.

**11 BLOOD SUGAR**—In about one third of my old cases, I have found it quite impossible to keep the blood sugar constantly at normal levels. I have witnessed no particular evil symptoms from permitting the higher blood sugar levels to exist, nor has there been evidence of gradual decline as has been predicted would occur were hyperglycemia allowed to persist. Some of these cases are very difficult to reduce, and apparently have hypoglycemic reactions at higher levels than the normal for this phenomenon. Three severe cases of this type after long treatment have recently shown evidence of improvement and are now within normal range. Many of this group have persistently high thresholds with little or no urine sugar. The other cases in the series are more or less variable.

**12 URINE SUGAR OUTGO**—Many of the old cases show 24-hour urine sugar in small quantities in spite of insulin dosage to the point of hypoglycemic reactions. This is due to the difficulty in synchronizing insulin activity with food absorption and metabolism. Apparently no harmful result is observed therefrom.

**13 BLOOD PRESSURE**—Occasionally in insulin-treated cases, a transient rise in both diastolic and systolic blood pressure is noted. I have observed this in 6 cases. In one case, a male who has had insulin for practically 4 years, there has been a permanent rise in systolic blood pressure of about 30 mm, together with slight changes in the retinal arteries, suggesting a vascular disturbance.

**14** No increased susceptibility to communicable or other disease has been noted in any of the insulin treated cases.

# STROGANOFF'S TREATMENT OF ECLAMPSIA, AND RUSSIAN PRENATAL AND CHILD WELFARE POSTERS

By STUART B BLAKELY, M D, BINGHAMTON, N Y

A DESCRIPTION of an "obstetric journey" to Russia last year appeared in the *American Journal of Obstetrics and Gynecology*, (June, 1926), as Correspondence. The chief objects of the trip were to learn at first hand

about the Stroganoff treatment of eclampsia, and to observe (hastily and incompletely) what the Soviet Government is doing for expectant mothers. Certain results of the quest seem to me to deserve further elaboration.

## STROGANOFF'S TREATMENT OF ECLAMPSIA

Prof B B Stroganoff of the State Institute for Obstetrics and Gynecology in Leningrad worked out a treatment of eclampsia in 1897 and published it with a report of 45 cases without maternal death in a Russian journal in 1899. To date he has observed over 900 cases of eclampsia and has used essentially the same method from the beginning. In the last 300 cases (under his "improved" method) he has had 2.6 per cent maternal mortality and 16 per cent fetal mortality—a record not approached by any other clinic. His treatment has been attacked and his figures questioned by many. To meet him is to remove any doubt about his ability, honesty and sincerity. It has never been demonstrated that any other cases than true eclampsia have been included in his series. The fact that most cases have no more than one convulsion after admission is no proof that the condition is less severe in Leningrad, but rather may be cited as evidence of the success of the treatment. His use of chloroform and the small amount of blood removed when phlebotomy is done have been most severely criticized, and many "modified" Stroganoffs are in use. He very pertinently asks on what basis of experience or results are such modifications made. The principles of his treatment are (1) To lessen the irritability of the nervous system by the prevention of irritation and by the use of narcotics, (2) To lessen the "toxins" in the blood by the production of perspiration, the administration of fluids, and venesection, (3) To maintain body functions.

The "improved" Stroganoff method is given in Hinselmann's "Die Eklampsie," in both Russian and German, but nowhere in American textbooks have I seen it in detail. It is worthy of the most serious study and application in view of our present knowledge of the condition, and of the methods and mortality in this country. The sources of the following outline of his "improved" method are personal talks and hospital rounds with Prof Stroganoff, and his articles in German, English and American medical literature.

### I REMOVAL OF IRRITATION, OR REDUCTION TO MINIMUM

- 1 Rest—absolute, in bed
- 2 Darkened room

3 Separate room and special nurse—constant observation of mother before delivery and of both mother and baby for 24 hours postpartum.

4 Elimination of noise—any and all as far as possible, which is possible much farther than most attendants have any conception of.

5 Avoidance of all manipulations, examinations, moving, etc., except as absolutely necessary (most of the procedures mentioned are entirely unnecessary) and then usually under chloroform. Therefore, no baths (cleansed with a wet towel if imperative), no lavage, no enemata or colon irrigations (unless bowel loaded), no packs, no hypodermoclysis or intravenous medication or fluid, no catheterization (except on admission and as indicated clearly), no abdominal or vaginal examinations (unless absolutely and definitely indicated, and the same for intravaginal and intrauterine procedures). The bed can be made or changed under chloroform, or directly after a fit, or when the narcotics have shown their full effect.

### II USE OF NARCOTICS (MORPHINE, CHLORAL HYDRATE AND CHLOROFORM)

It is *very* important that *enough* be given the first 4-5 hours to control the convulsions for this is the first principle of the method. If necessary the larger doses may be given and the schedule hurried a bit.

#### 1 Morphine Sulphate and Chloral Hydrate

##### a Doses and Frequency—

First—morphine sulphate	0.01	0.015	0.02	gms
End 1st hr—chloral hydrate	15	20	25	gms
End 3rd hr—morphine sulphate	0.01	0.015	0.02	gms
End 7th hr—chloral hydrate	15	20	25	gms
End 13th hr—chloral hydrate	10	15	20	gms
End 21st hr—chloral hydrate	10	15	20	gms

The metric system is used. The middle figures are the average doses. For weaker patients and with lighter attacks (e.g., postpartum) the smaller doses may be used, for stronger patients and severe eclampsia, the larger doses—even up to morphine sulphate 0.03 gms and chloral hydrate 90 gms in 12 hours. The patient must sleep or slumber, rousing slightly with the pains. If 14 hours without a convulsion, lessen the dose of chloral. On the second day and no convulsions, give chloral hydrate 10-15 gms t i d.

b *Method of Administration*—Morphine by hypodermic and under chloroform—both doses. The chloral is given by mouth with 100 cc milk if conscious, if unconscious, by rectum with milk and saline solution aa 100 cc—the first two doses usually under chloroform, the other doses not if no fits for 12 hours

2 *Chloroform*—10 to 20 drops or more at a time, usually not over 10 cc. in 12 hours, though 40 cc has been given to a "strong" patient in that time. It is useless to try to give chloroform during a convulsion. Chloroform is given for all examinations, manipulations, etc., when a convulsion is likely to occur, when giving medication, as outlined in the preceding paragraph, during the first two intervals between medication for 10 to 20 minutes if prodromata of a fit appear, at the birth of the head, at and directly after the birth of the placenta, 10 to 15 cc. Prodromata of a convulsion are headache or increase of headache (complaint if conscious), restlessness, twitching of face, hands and feet, dimming of vision, increase of blood pressure.

### III VENESECTION

Used since 1911 in 10 to 15 per cent of cases 400 cc. of blood is removed. It is indicated if convulsions recur two or three times, if one very severe occurs, or if they continue in spite of the narcotics, also in the presence of pulmonary oedema, or a hard pulse postpartum. It is not indicated if delivery is expected within two to four hours.

### IV DELIVERY

As soon as possible without danger to mother or child—especially the former, and under narcotics. The membranes may be ruptured artificially when the external os is dilated two fingers in a multipara, or three fingers in a primipara. A careful forceps or version (latter rarely in primiparae) may be used to hasten delivery—of course when conditions are suitable and not forced. The following procedures are *not* done

—accouchement force, introduction of bags, Caesarian section

### V MAINTENANCE OF BODY FUNCTIONS

1 *Skin and Kidneys*—warm light coverings, hot water bottles to feet and kidney regions (care about burns!), hot weak tea and milk at least 500 cc aa in 24 hours—if unconscious, milk and saline at least 500 cc aa by rectum in the same period

2 *Lungs*—fresh air. During and after a convulsion it is very important and valuable to administer oxygen. All hindrances to free respiration should be removed, especially in feeble patients. The patient should lie chiefly on the right side, but her position should be changed at least every four hours. The mouth and nostrils should be carefully cleansed and kept free from mucus, vomitus, blood, etc.

3 *Heart*—if weak, or after several convulsions, or over 100, digitalis is given. If very weak or rapid, caffeine, camphor, etc.

Toward the end of the first day under proper treatment one may expect the following favorable symptoms—cessation of convulsions (in over 80 per cent of the cases these cease within 24 hours, if there are no convulsions for 12 hours, in only 34 per cent do they recur), clearing of sensorium, increase of urinary output, perspiration, lessening of headache, lowering of blood pressure. Many cases get over their eclamptic attack and go home undelivered, though in the majority of cases labor starts spontaneously. An increase of narcotics is indicated if the pulse continues hard and tense, if severe headache persists, if there is unrest, or continued coma, if the convulsions continue. Only very rarely is an obstetrician driven to a forced delivery of an eclamptic. Occasionally an eclampsia proceeds to a fatal termination in spite of all efforts.

To realize the value of the method and to get results the treatment must be prompt, strict and thorough. If it is not all three, it is not Stroganoff's.

### RUSSIAN POSTERS ON PRENATAL AND CHILD WELFARE WORK

Down in Moscow the Department of Maternal and Infant Welfare of the central Soviet government faces a colossal task. Consider some of the elements of the problem—a country occupying one-sixth of the world's land area, a population of over 130 millions, 90 per cent rural and possibly 80 per cent illiterate, of divers races, languages, habits, customs and beliefs, a conglomerate of peoples, the majority exploited and oppressed for centuries by emperor and priest, demoralized by years of war, revolution, famine and disease, a welter of humanity, in a high degree superstitious, hostile to change, suspicious of government. I have seen no figures for the

maternal death rate, we cannot boast of very accurate ones in this our supposedly enlightened country. One of the child-welfare posters states that of 100 children born, 26 die in the first year. It is probably not too high an estimate. But the Department has made a start. It is poor in money, personnel and equipment. It works and hopes in the face of almost overwhelming odds. It is entirely within its rights to ask that the results of its works be not yet judged, it is highly proper for it to ask for time for such a task. A half century would be short. I definitely feel—possibly on insufficient evidence—that they are earnest and sincere and are really

striving to do something for the common woman of Russia and her child

It is not possible to enter into a discussion of the many ways and means used in the propaganda for the health of mother and child. One, however immediately attracted my attention and impressed me profoundly—their prenatal and child-welfare posters, that are displayed in hospitals, dispensaries, creches, summer nurseries, clubs, community houses, factories, co-operative stores, etc. In 1924, more than 80,000 were distributed. They are admirably suited for their purpose. Black and white prints give no idea of the brilliant coloring (so dear to the Russian heart), the artistic design and striking beauty as do the originals or colored lantern slides. Untrammelled by convention in conception or execution they are entirely original, unique in their field and unsurpassed, I believe in the world today. Ten of these posters (of course such reduced in size) are printed in the pages following, accompanied by a rather literal translation of the Russian texts and descriptions (readers familiar with Russian please be merciful!) In brackets are some comments of my own that may help to a better understanding of the posters.

Poster No I

*Take care of the woman-mother*

The owner watches his pregnant horse and pregnant cow, but has no pity on his pregnant wife

Peasants! Relieve her of hard labor, do not lift anything heavy—this may make her and her child perish [Typical peasant scenes]

Poster No II

*What every woman should know*

Female sexual organs—normal condition

Uterus at the ninth month of pregnancy

Uterus after delivery. It is a big open wound and at that time is easily infected. Watch cleanliness and do not work for seven days. [In Moscow wax models of these figures were accessible to the general public]

Poster No III

(UPPER LEFT)

*What every woman should know*

Do not drink any alcoholic liquor. Do not lift any heavy weight. Bathe yourself often. Change your underlinen. During pregnancy show yourself several times to the doctor. [A prenatal consultation]

(UPPER RIGHT)

Swelling during pregnancy is a sickness. Consult the physician, pay no attention to the midwife

(LOWER LEFT)

The birth with the assistance of the midwife

b *Method of Administration*—Morphine by hypodermic and *under chloroform*—both doses. The chloral is given by mouth with 100 cc milk if conscious, if unconscious, by rectum with milk and saline solution aa 100 cc—the first two doses usually under chloroform, the other doses not if no fits for 12 hours

2 *Chloroform*—10 to 20 drops or more at a time, usually not over 10 cc. in 12 hours, though 40 cc has been given to a "strong" patient in that time. It is useless to try to give chloroform *during* a convulsion. Chloroform is given for *all* examinations, manipulations, etc., when a convulsion is likely to occur, when giving medication, as outlined in the preceding paragraph, during the first two intervals between medication for 10 to 20 minutes if prodromata of a fit appear, at the birth of the head, at and directly after the birth of the placenta, 10 to 15 cc. Ten of these posters (of course much reduced in size) are printed in the pages following, accompanied by a rather literal translation of the Russian texts and descriptions, readers familiar with Russian please be merciful! In brackets are some comments of my own that may help to a better understanding of the posters.

Poster No I

*Take care of the woman-mother*

The owner watches his pregnant horse and pregnant cow, but has no pity on his pregnant wife.

Peasants! Relieve her of hard labor, do not lift anything heavy—this may make her and her child perish [typical peasant scenes]

Poster No II

*What every woman should know*

Female sexual organs—normal condition

Uterus at the ninth month of pregnancy

Uterus after delivery. It is a big open wound and at that time is easily infected. Watch cleanliness and do not work for seven days. [In Moscow wax models of these figures were accessible to the general public.]

Poster No III

(UPPER LEFT)

*What every woman should know*

Do not drink any alcoholic liquor. Do not lift any heavy weight. Bathe yourself often. Change your underlinen. During pregnancy show yourself several times to the doctor. [A prenatal consultation.]

(UPPER RIGHT)

Swelling during pregnancy is a sickness. Consult the physician, pay no attention to the midwife.

(LOWER LEFT)

The birth with the assistance of the midwife

often results in the serious illness and even the death of the mother and child

(LOWER RIGHT)

Knowledge and cleanliness are the guarantees of health. The accoucherka has studied and knows how to correctly care for mother and child. Call an accoucherka (a sort of "nurse-midwife") [Contrast the two lower pictures]

Poster No IV

(UPPER LEFT)

From what do a lot of children die by us till they reach the age of one year?

Chewed nipples, early adding of cereals, dirt and not knowing how to care for the baby are reasons that cause the loss of so many babies in the woods (i.e., peasant villages and homes)

(UPPER RIGHT)

The more educated the mother, the less children die [Contrast the surroundings and bearing of the two mothers]

(LOWER LEFT)

Out of a 100 newborn there die in the first year of life in Switzerland 9, in England 14, in Italy 17, in Germany 20, and in Russia 26. The most children of all die with us [In the original poster the national costumes are in color]

(LOWER RIGHT)

Out of a 1000 newborn there die in the first year of life in the spring, 73, in summer 144, in autumn 63, in winter 67

Watch your babies, especially in the summer. Most of all children die of summer diarrhoea. [Note the changing foliage of the seasons and in the last panel the snow, also little crosses in the graveyards]

Poster No V

(UPPER LEFT)

*How to feed the baby by the breast*

The breast cannot be substituted by anything else. Cow's milk—6 months—8 pounds, breast milk—same age—18 pounds. When breast-fed the mortality is seven times less [The Russian pound is not the same as ours, note the difference shown in the state of nutrition]

(LEFT CENTER)

The weight of a healthy child is usually two times its birth weight at 6 months, and three times at a year

At birth, 8 pounds (3,200 gms), 6 months, 18½ pounds (7,300 gms), 1 year, 25 pounds, (10,000 gms)

(CENTER)

Take the baby with you into the fields. Feed the baby up to the sixth month only with the breast—not to give any bread or cereal [The peasant woman can grasp this, special emphasis has been laid on the establishment of summer nurseries for nursing mothers working in the fields]

(UPPER RIGHT)

Feed the baby not more than seven times in 24 hours. This shows the milk in the stomach of the boy—immediately after feeding, one hour after feeding, two hours after feeding, three hours after feeding [Note the changing expressions on the baby's face—from satisfaction to hunger—as the milk level lowers in his stomach]

(RIGHT CENTER)

After six months it is necessary to help the breast. Semolina, 6 months, potato flour and fruit, mashed potato, mashed carrots, mashed turnips, 7 months, cow's milk, soup, bread, 9 months, raw fruits (apples, pears, plums, cherries, currants), meat 12 months

(LOWER LEFT)

What a nursing mother is allowed to eat (there are shown fish, fowl, beef, cucumbers, lobsters,

carrots, cabbage, apples, cherries, currants, pretzels, rye bread, eggs, milk, cocoa)

(LOWER RIGHT)

These are not allowed for a mother who nurses (there are shown home-distilled vodka, beer, wines, liquors, garlic, onions, horseradish, relishes) [Hardly possible to be more graphic than these last three pictures]

Poster No VI

(UPPER LEFT)

*How to care for the baby*

Do not bandage the child, and do not dress it at home with a bonnet Do not bundle it up, either summer or winter

Bandaging hinders the child to breathe and grow, and brings out skin irritations and different rashes

(UPPER RIGHT)

Dress the child thus, so that it can freely move the hands and feet

(LOWER LEFT)

The cradle is harmful Again, the cradle makes the child dizzy Do not swing the child, either in the cradle or in your arms

(LOWER MIDDLE)

Do not put the child to sleep with you The child might be overlain and might contract some disease

(LOWER RIGHT)

Buy a clothes basket, and that will make a cheap and healthy bed for the child

Poster No VII

(UPPER LEFT)

Cleanliness, sunshine and fresh air promote the health of the child Dirt is the source of disease

(UPPER RIGHT)

Bathe the child every day, change its clothes often, wash your hands often and keep your rooms clean [Contrast the details of the two rooms]

(BELOW)

Strong sunshine and light are the worst enemies of disease. Be out of doors with the baby much of the time, both winter and summer Don't be afraid of the sun and light Air your rooms every day

Poster No VIII

(UPPER LEFT)

What is rickets (the English sickness) and how to fight it?

Improper feeding of cow's milk, close air, darkness, dampness—these are the causes of rickets, the English sickness [Term derived from the old treatment of this disease in England by the King's touch]

(UPPER RIGHT)

Rickets cripples children for their whole life. It makes them bow-legged, hunchbacked—and many die of it. The remainder that survive often get sick with tuberculosis. [Note the unhygienic conditions in these two rooms—the dirty bottles, the filth, the dark close rooms, the animals, the rickety children, the tuberculous man.]

(LOWER LEFT TEXT)

How to prevent the child getting rickets—the English sickness

(LOWER RIGHT TEXT)

Feed to the sixth month only with the breast. After the sixth month add cereals and vegetables. Do not be afraid of air and sunshine. [Contrast in detail the lower picture with the two above.]

Poster No IX

(ACROSS TOP)

The preservation of motherhood and childhood in the villages is the work of the hands of the peasant women themselves

(UPPER LEFT)

The consultations (dispensaries) will teach you to guard your baby from illness

(UPPER RIGHT)

The best and safest place for a woman to give birth is the hospital maternity ward. Remember that in abnormal cases the help of the doctor cannot be substituted

(CENTER)

The local co-operative societies and mutual aid committees should come to the help of the mother and child

The local doctor should set aside one day a week to accept mothers and breast children

We don't want to trust the midwives any more. We demand the accoucherok (plural form)

You should help us build summer nurseries and dispensaries

Demand a delivery department in the branch medical hospital. [Note the peasant women gathering, the spellbinder, and the wall placards.]

(LOWER LEFT)

Summer nurseries free the mother from worry and preserve the health of the child. [Much emphasis on this.]

(LOWER RIGHT)

Defend yourselves from flies. We demand clean and dry diapers. Breast of the mother. Clean air and light. We demand healthy parents. We demand trained nurses. No midwives. We demand vaccination. [A soapbox orator and a parade of banners with devices!]

Poster No X

(ACROSS TOP)

Abortion, induced by the midwife or accoucherka, not only cripples the woman, but often causes death

(LOWER LEFT TEXT)

Every abortion is harmful

(LOWER RIGHT TEXT)

A midwife or accoucherka who does it commits a crime

(UPPER LEFT)

At the house of the abortionist. [Note the attitude of the woman and the assurance of the abortionist with bottle of abortifacient and bodkin in her hand.]

(UPPER RIGHT)

The result of the abortion. [The hospital ward.]

(LOWER CENTER)

The death of the woman aborted. [Note the large towels that are used to support the coffin, these are furnished by the family of the deceased and become the property of the bearers. A homely gathering in the country cemetery about the open grave—the last chapter of the tragic story.]

## THE DIAGNOSIS OF AFFECTIONS OF THE HIP JOINT\*

By ARTHUR KRIDA, M D, F A C S, NEW YORK, N Y

**A**FFECTIONS of the hip joint at all ages manifest themselves primarily as disorders of function of the joint. The primary aim of treatment is conservation of function. Treatment, to be most effective, must be instituted early. The institution of treatment must wait upon the recognition that a disorder exists, and upon its diagnosis. The responsibility for the recognition of the fact that a hip joint affection exists falls nearly always upon other than orthopedic specialists, its differential diagnosis is usually simple, sometimes difficult, and occasionally exhausts the diagnostic resources of the orthopedic surgeon.

Frequency and age incidence are often convenient pegs upon which to hang a diagnosis. With this in mind, I have analyzed the case histories of hip joint cases which presented at the Hospital for Ruptured and Crippled during a single year (1925). At this hospital a regional system of classification of case histories has been in use during the last three years. The material here analyzed is filed under the subdivisions of the caption of "Hip Joint and Hip Region," and includes 458 cases, 152 were cases of minor and unclassified conditions, in a number of which the case histories were too fragmentary to substantiate a diagnosis.

A further group of 55 cases were listed as "Gluteal Myositis." The latter is a semi-medical type of diagnosis. It is mentioned here because it is still much used, but it should be emphasized that the painful "lumpy" condition of the gluteal muscles which it denotes is most often an expression of chronic static insufficiency of the lower back.

Excluding these two groups, 251 cases remain which were subdivided as follows:

Unclassified Fractures, 8, average age 55

Fractures of the Femoral Neck, 28, average age 56

(11 fresh fractures, 17 un-united)

Displacement or Separation of the Upper Femoral Epiphysis, 13, average age 12

Acute Destructive (Septic) Arthritis, 1, age 19

Sequellae of the above (Deformity, Pathological Dislocation), 16, average age 25

(Average age of onset, 7, onset in 6 of 16 cases, under 2)

Chronic Infectious Arthritis, 16, average age 16

Osteoarthritis, Monoarticular Arthritis Deformans, 38, average age 51

Chronic Destructive Non-Tuberculous Disease, 2, average age 17

Tuberculosis of the Hip, 39, average age 14  
Sequellae of the above (Inactive Disease, Deformity, Dislocation), 22, average age 26

(Average age of onset of 50 cases of above two groups, 8 years. 27 of 50 cases onset under 5 years.)

Congenital Dislocation, 65, average age 6  
(45 of 65 cases were under 4)

Osteochondritis Juvenilis Coxae, Calve-Legg-Perthes' Disease, 3, average age 8

It will be seen from the above that congenital dislocation and tuberculosis of the hip (at least in so far as it concerns the age of onset) is most frequent in childhood, and that osteoarthritis and fracture of the femoral neck is most frequent in the declining years. The period of adolescence is noted by the medicine of epiphyseal separation and chronic infectious arthritis. The young adult seeks relief most often for the sequellae of acute destructive arthritis, although the initial disease occurred many years before.

### DIAGNOSTIC METHODS

#### (a) Physical Diagnosis

The examination should obviously be conducted after the patient has shed his clothes. Abnormalities of gait, station and posture in recumbency may then be noted. Limp and atrophy are outstanding features which may be elicited in this stage of the examination. Local heat, infiltration and tenderness should then be sought. After this should follow the examination for limitation of motion, which should always be conducted with care. There is nothing to be gained from inflicting needless pain upon the patient by this manipulation. The extremes of motion should be noted, and it is well to bear in mind at this time, that if motion is restricted in all directions, that an arthritis exists.

#### (b) Mensuration

In all distortions about the hip joint, measurements should be made. The discussion of the interpretation of measurements of the length of the lower extremities and of distortions about the hip joint is apt to be befogged unless a very few simple and basic principles be kept in mind. The serious student of these matters is discouraged from the very beginning by tables of relations between "actual" and "practical" shortening, and by Kingsley's table, still quoted in textbooks, for the measurement of flexion deformities, when after all the matter is not so complicated.

In the normal individual, in the upright position, the anterior superior spines are on a plane parallel with the floor. If this plane deviates from the parallel, and abnormality exists. For

\*Read at the Meeting of the Nassau County Medical Society, September, 1926

practical purposes, pelvic tilt is dependent upon one or more of three factors (a) change in length of the component bones of the lower extremity, (b) upward displacement at the hip joint of the extremity as a whole, (c) primary change in the angle at the hip joint, (flexion, abduction, adduction) The determination as to the relative responsibility of each of these factors may be made with an approximation to accuracy sufficient for clinical purposes, with a tape measure

The examination is made with the patient on his back. The pelvis is made level, and the normal limb is placed in its proper relation to the pelvis. The measurement is made from the anterior superior spine to the internal malleolus. This is the measurement of "actual" length. If the abnormal limb may be brought to a similar relation with the pelvis, and if the measured length from the anterior superior spine to the malleolus be found to be less than the other, it will at once indicate either a shortening of the component bones of the lower extremity or an upward displacement of the extremity as a whole (dislocation)

If the abnormal limb cannot be brought into its proper relation with the pelvis, the nature and degree of its distortion with relation to the pelvis is to be determined. For distortions in the abduction-adduction plane, the center of a line joining the anterior superior spines may be considered, for purposes of record, as the center of rotation. The angle which the lower extremity makes with this line may be determined with sufficient accuracy by inspection, and is thus recorded in degrees of abduction or adduction.

Minor grades of restriction in the range of hyperextension are determined by turning the patient over on his face, testing the range in the normal limb by placing one hand on the pelvis and the other beneath the knee, and hyperextending the extremity. Slight deviations in the abnormal limb are at once evident by comparison.

Grosser flexion distortions are determined with the patient on his back. The normal limb is flexed at the hip until the lumbar spine rests on the table. The abnormal limb will make an angle with the table, the degree of which may be determined by inspection, and so recorded.

The significance of noting distortions in those cases where the abnormal limb cannot be placed in symmetry with the pelvis lies in the fact that it modifies to a slight extent, the measurement of "actual" length. "Actual" length measurements are lessened by abduction and flexion.

Measurements of "actual" length lose much of their significance in the presence of gross distortion at the hip. In such instances a measurement which more nearly expresses the static relations of the distorted extremity is used. This is the measurement of "practical" shortening.

This is made with the patient lying on his back, with the lower extremities placed in line with the trunk. For static purposes, a point corresponding to the umbilicus is considered as the fixed point, and the measurement is made from this to the malleoli.

In a practical way it may be stated that the commonest finding in nearly all hip joint affections is restriction in range of abduction and extension, in other words, a flexion-adduction deformity.

### (c) LABORATORY AIDS

Laboratory investigations are used as for disease or abnormality elsewhere in the body. The degree to which various investigations are carried, the limitations of the various procedures, and the interpretation of the results are matters which are determined by the general pathological experience of the individual surgeon.

### (d) X-RAYS IN DIAGNOSIS

In hip joint affections, the attempt to utilize the X-ray as a diagnostic short-cut too often results in dismal failure. The X-ray yields nothing in acute sepsis of the joint and in the earlier months of a tuberculous or other chronic infection. The masters of orthopedic surgery who wrought in the pre-X-ray era elaborated a pathology and therapeutics which in many instances has stood the test of time. One need refer only to the work of Lorenz on congenital dislocation and to that of Royal Whitman on fracture of the femoral neck and on epiphyseal displacement as examples. The point is made to illustrate the fact that X-rays cannot be made to take the place of trained clinical investigation. On the other hand, X-rays are frequently of great diagnostic and prognostic significance. Occasionally, the diagnosis hinges largely on the X-ray plate (Perthes' Disease, sub-luxation).

### FRACTURE OF THE NECK OF THE FEMUR

The fracture of the hip in old people is a picture so familiar to all of you that it hardly merits special mention. And yet there are aspects of this condition which will bear reiteration. A person over 55 years of age who makes a misstep or twists his leg in the dark, falls down and is unable to get up, is apt to have a fracture of the femoral neck. There is no such thing as a "sprained" hip in an aged individual. The hip is broken. The patient takes to his bed. There is a great deal of disability, and a great deal of pain on movement, and pain is often referred to the inner side of the knee. In a typical case, the diagnosis can confidently be made on such a history.

Confirmatory evidence is found by inspection of the extremity. It is outwardly rotated, frequently to a degree so that the outer border of the foot rests on the bedclothes. Little is to

be gained by moving the hip except the expression of a good deal of pain, and nothing is to be gained by measurement, since the fragments have not been sufficiently displaced to alter the actual length measurement. The X-ray will demonstrate the fracture, if the reader of the plate is familiar with the clinical picture. Otherwise it may escape detection, since the line of cleavage in the cancellous structure of the femoral neck is often thin and faint, and no gross displacement is noted.

The above description applies to a patient seen a few hours after the fracture. At a later time, the details are more evident, and the X-ray shows the progressing deformity.

The patient seen in the stage of non-union presents a fairly characteristic picture. He gets about with difficulty, and with the aid of crutches. The outstanding symptoms are great pain and disability. The limb is atrophied, shortened and outwardly rotated. Movement at the hip is restricted, abduction being entirely limited. The symptoms are due to friction of the displaced fragments, and to a chronic traumatic arthritic change in the hip joint. It must be stated however, that occasionally a younger and more robust individual will survive the stage of friction of the fragments, and either by complete absorption of the neck or great upward riding of the distal fragment, make for himself a variety of unstable pseudarthrosis which is comparatively painless.

#### EPIPHYSEAL FRACTURE

This somewhat uncommon condition is associated with the name of Royal Whitman, who described it first in 1890.<sup>(1)</sup> It consists in a variable degree of displacement of the upper epiphysis at the epiphyseal line, in which the epiphysis rotates about the neck in a downward and backward direction, in other words, the epiphysis to a variable extent, slips off the femoral neck. The displacement above described determines the nature of the disturbance of function, there is limitation of abduction, flexion and internal rotation.

The condition occurs in the period of adolescence, and most often in large, fat children of the "pituitary" type. The average age in 13 cases was 12 years, the youngest was 10, and the oldest 15. There is usually a history of injury, though the latter may be slight. There is complaint of pain and limp. The diagnosis may be made from the characteristic limitation of motion, and is confirmed by the X-ray.

#### OSTEOARTHRITIS

This is the common form of "stiff hip" of old people. It may be noted that it corresponds in frequency, and practically in age distribution, with the group of fractured hips in the above analysis.

It is a very slow-going progressive process corresponding in all essentials with the similar common affection of the knee joint. Its first indication is usually a sensation of stiffness of the joint on arising from a chair. There is less resistance to fatigue. Pain is generally a later symptom, although occasionally it may be present early. Frequently it is referred to the outer side of the thigh or the inner side of the knee. The pain of the later stage may be very severe. The diagnosis is simple, there is flexion-adduction reformity, usually with internal rotation. The X-ray is characteristic.

#### ACUTE DESTRUCTIVE (SEPTIC) ARTHRITIS

The relatively large number of patients seeking relief for the sequellæ of this condition emphasizes the importance of prompt diagnosis and of operation in its earliest stages.

The average age of onset in 16 such cases was 7 years, and in 6 of these cases, it was under 2 years. It would seem that a hip condition with an acute onset in a young child, with pain, high fever, swelling and extreme tenderness, would always justify an immediate arthrotomy. The occasional case which would reveal a mistaken diagnosis would not be harmed by such a procedure, which in itself would in no way militate against the application of a retentive appliance. It is to be expected that on the other hand, early and adequate drainage would materially lessen the destructive nature of the process.

#### CHRONIC INFECTIOUS ARTHRITIS

A review of the histories of these cases discloses that their nature is essentially benign, and corresponds to the course of similar lesions elsewhere in the body. The X-ray demonstrates no bony pathology. It must be stated, however, that the last analysis, the virulence of the infecting organism, and the resistance of the individual, determine the degree to which joint damage may be incurred. The distinction between this and chronic destructive arthritis is largely an artificial one, and is dependent upon the above factors.

#### TUBERCULOSIS OF THE HIP

This is the familiar "hip disease" of medical phraseology. In incidence, it bulks largest among the inflammatory processes involving the hip joint. It is the most important and the most serious of the diseases of the hip joint.

As a preliminary statement to the discussion of the diagnosis of this disease, it must be emphasized that it must be differentiated insofar as that is possible, from all other conditions involving the hip joint.

A chronic coxitis in a young child must be assumed to be tuberculous unless it can be proved otherwise, in the present state of our knowledge of this condition. A definite diagnosis may be

extraordinarily difficult in the early cases, and it must be repeated that the X-ray is of little assistance in the early months of the disease Girdlestone<sup>(2)</sup> has summed the matter up admirably in his recent book on "Tuberculosis of the Hip" where he states "the lack of this (a definite test, comparable to the Wassermann test) is a very great handicap, for the diagnosis rests on probabilities until either destruction has advanced to such a degree as makes the radiogram evidential, or abscess formation renders a conclusive test possible in the finding of tubercle bacilli, microscopically or by animal inoculation, in the aspirated fluid"

According to Girdlestone (p 24) such fluid may be obtained in about  $\frac{1}{2}$  of cases, and that furthermore tubercle bacilli may be found in smears of "cold" pus by persistent search in 95% of cases

The tuberculin tests possess the same significance here as with tuberculosis elsewhere in the body Positive reactions in young children are suggestive, negative reactions tend to rule it out

The average age of onset in 50 of 61 cases above cited, in which the point was covered, was 8 years, in 27 of these it was under 5 Since early diagnosis is most important, it is urged that every possible means be taken to assure it If after the available means have been exhausted, and doubt still exists, the therapeutic test must be employed

#### CHRONIC DESTRUCTIVE NON-TUBERCULOUS DISEASE

It is generally assumed, although perhaps not always definitely so stated, that a chronic destructive lesion, unaccompanied by productive changes, is tuberculous Two such cases are included in the above analysis, and a third has been under my observation in another hospital, in which diseased tissue removed at operation showed chronic inflammatory change without tubercle formation The age of onset in these cases was 13, 21, and 22 years The observation is made without attempting to draw therefrom conclusions which would place in this category

any considerable number of cases hitherto classed as tuberculous

#### OSTEOCHONDRITIS JUVENILE COXA CALVE—LEGG—PERTHES' DISEASE

In general, this disease in its earlier manifestations bears a close resemblance to tuberculosis It is however a benign condition which yields speedily to far less drastic treatment than that required in tuberculosis In the material above cited, the case records and X-rays were sufficiently definite in three cases to warrant the diagnosis

The characteristic changes, which occur mainly in the epiphysis, consist of fragmentation, sclerosis, and regeneration The regeneration may be accompanied by a permanent modification of contour of the femoral head, a circumstance which has led in some clinics, to the designation of "coxa plana"

When the condition is fully developed, the X-ray demonstrates the above changes

#### CONGENITAL DISLOCATION

These cases constitute the largest group in the above analysis The age at which treatment is instituted is a crucial matter in the outcome of these cases The average age at which patients were brought for treatment was 6 years, and in 45 of the 65 cases it was under 4

The diagnosis becomes evident when the child begins to walk If one hip is displaced, the child limps, if both, he waddles The trochanter is felt above its normal position, and the head of the femur is felt outside the acetabulum The X-ray is conclusive

The treatment at this stage is less trying to the parents, if the child's sphincteric control has been established There is every reason to begin it as early as possible

### WHEN TO OPERATE IN CASES OF PEPTIC ULCER\*

FRANK H LAHEY, M D, F A C S—SARA M JORDAN, M D, BOSTON, MASS

THE best test of one's surgical judgment is the application of it to one's own person

Especially is this true in these days of uncertainty and conflicting data with regard to the use of gastric surgery in cases of gastric and duodenal ulcer If every surgeon would consider his patient's ulcer as his own, and to all the available data of the case add the ques-

tion, "What would I want done with this ulcer if it were mine?"—there would arise a more uniform procedure in the treatment of the ulcer

A clearly defined policy is of great assistance in arriving at a satisfactory decision in the individual case The construction of such a policy involves first of all a consideration of the basic pathology of ulcer, the etiological factors which contribute to the so-called ulcer

\* Read at the meeting of the New York County Medical Society, Academy of Medicine, New York October 25 1926

diathesis, the advantages and disadvantages of medical management, and finally the end results of surgery

The first consideration, namely, the basic pathology of ulcer is still obscure. It is certainly simplest and possibly nearest to the truth, to regard the ulcer, like so many other diseases, as the result of diverse causes. That a neurogenic factor is present and of great importance, is apparent, both from clinical observation and the experimental production of the ulcer. It is easy to conceive of this neurogenic factor as a power behind the ulcer diathesis, and it is likewise possible to reconcile it with the other etiological factors which have been held responsible for the genesis of ulcer.

A nerve irritability, inducing spasm of the muscle, might conceivably be a precipitating or an adjuvant factor, whether the other factors were thrombosis of the capillary, with necrosis of the mucous membrane, or gastritis, or both. The neurogenic factor, then, must be borne in mind when treatment of ulcer is considered. It may well be the underlying factor in the so-called ulcer diathesis. Possibly, also, a chemical dyscrasia underlies the neurogenic factor.

But all these considerations still belong to the realm of theory. We may continue to surmise and theorize and work upon the problem of the basic pathology, and continue to indict the so-called ulcer diathesis for recurrence, but for the very reason that the etiology is still uncertain, we are confronted with the necessity of treating the ulcer as if it were a pathological entity.

The first and one of the most important considerations in the treatment of ulcer is the accurate diagnosis of the condition. There is a tendency even today to accept a history of indigestion with an X-ray report of a defect as conclusive evidence of active ulcer. Where protracted medical management is contemplated, it is essential that this should be correctly applied to a real lesion. A carefully taken history with stress upon the character of distress, time of its occurrence, relief, remissions, constancy, or change in character of symptoms, actual observation of the patient after distress has been stirred up, and observation of relief by cold food and alkalies, gastric analysis, stool examinations, and finally fluoroscopy are all essential to the diagnostic routine.

Success in treatment has undoubtedly been obtained by both surgical and medical methods. Cures have undoubtedly been spontaneous. In the induced cures, the control of the free hydrochloric acid is considered by most observers to be the factor of prime importance. Medical management neutralizes the acidity temporarily,

gastro-enterostomy usually decreases or neutralizes the acidity permanently, subtotal gastric resection decreases or removes the acidity and the ulcer. Relief of symptoms occurs with all these forms of treatment, but with the latter with more completeness and certainty.

If the ulcer is not to be removed as by partial gastrectomy, neutralization of the free hydrochloric acid is the object of treatment for the relief of symptoms and the healing of the ulcer. Relief of symptoms and healing of the ulcer when it occurs is obtained by neutralization of the free hydrochloric acid, either by accurate medical management or by gastro-enterostomy. Recurrence of the ulcer or occurrence of a new ulcer may occur with either of these methods of treatment. With the complication of an unrelievable pyloric obstruction, gastro-enterostomy serves the double purpose of providing a new channel for the passage of food and a means of neutralizing the hydrochloric acid.

The chief advantage of medical management is its comparative safety. There is no operative risk. Perforation has not occurred in our experience of the past three years in cases under medical management. Recurrent hemorrhage has occurred in 12 per cent or two out of one hundred and sixty-one cases. Eighteen cases of this series had massive hemorrhage before treatment. In both cases in which a second hemorrhage occurred the recurrent hemorrhage was less severe than the one which occurred before the beginning of treatment. A danger arising occasionally from this method of treatment itself is alkalosis. In 18 per cent of our cases treated intensively with alkalies, dryness of the pharynx, nausea and vomiting, pruritus, albuminuria, and stupor have been observed. All of these symptoms were relieved by the omission or reduction of alkalies and in only once case did medical management fail for this reason, and surgery become necessary.

It may be assumed, therefore, that the dangers of medical management are practically negligible. The disadvantages of its use lie in the awkwardness of constant neutralization. It is a commonly used argument against medical management that it can be carried out only by people of considerable intelligence and leisure. However by painstaking instruction in the necessity for half-hourly neutralization with either food or alkalies, the patient is led to adapt this treatment to his mode of living. In the experience of our Clinic it can be accomplished, with the aid of thermos bottles in individuals pursuing all forms of occupations—policemen travelling salesmen, doctors nurses mill workers teamsters. In fact, the only patient in our Clinic who has found it impossible

was an old man of eighty, retired from active business, and with nothing else to occupy his attention

A carefully outlined regimen, with careful check-up observations during an over-night stay in the hospital, every two months for a year, has been found valuable from the standpoint of the patient's safety and loyalty to his purpose

With regard to the other disadvantage of medical management, namely, the recurrence of symptoms, statistics are perhaps more misleading than in any other field of medicine. Medical management means to some physicians the use of a more or less accurately prescribed diet which the patient uses more or less accurately, with no preliminary bed rest, and no persistent attempt to neutralize gastric acidity. Yet many surgeons accept the results of this method of treatment as the results of medical management. Their indications for surgery will inevitably be more frequently encountered than in the Clinic where a systematic and well controlled form of treatment is insisted upon

In our Clinic, where in the past three years careful medical management, with neutralization by the Sippy method has been carried out (by the Gastroenterological Department), in association with the Surgical Department, and an effort is being made to follow up all patients for ten years after the beginning of treatment, results of medical management have so far been satisfactory enough, so that it is a routine procedure to submit the new case, unless it is an acute perforation, to our medical attempt to heal the ulcer. It is not unusual for a referred case to give a history of the unsuccessful employment of previous medical treatments and to come to the Clinic prepared for surgical treatment, only to be submitted again to a more accurate medical management with relief of symptoms. Only in cases of gastrojejunal ulcers do we hesitate to recommend medical management because of its less satisfactory results, and this fact adds further grounds for preliminary caution in relation to the employment of gastro-enterostomy

The routine use of medical management, in order to be a safe procedure, must be affiliated with a definite policy for the substitution of surgery, when this is indicated. Our policy as to the question "When to operate in Peptic Ulcer," is to operate,

- 1st In cases of perforated ulcer
- 2nd In unrelievable obstruction
- 3rd In cases of recurrent hemorrhage
- 4th In all cases where there is a reasonable ground for suspicion of carcinoma
- 5th In cases of failure with medical management

With regard to the first indication, there can be no diversity of opinion. The acute perforated ulcer is a surgical emergency

The second indication, unrelievable pyloric obstruction, occurs very infrequently in the non-malignant pyloric or the duodenal lesion. Numerous cases of apparent obstruction have been relieved within three weeks of careful management and presumably cicatricial tissue proven to be in large part the oedema and spasm of an acute inflammatory process. It is a familiar fact that the so called hourglass deformity usually proves to be spasm or the result of adhesions. Obstruction due to ulcer medically unrelievable is, therefore, in our experience, a rarity

Recurrent hemorrhage, in spite of relief of symptoms and other evidence of healing of the ulcer, makes it necessary to substitute surgical for medical measures. Surgery in such cases, however, should be directed toward the removal or control of the bleeding vessel. Gastro-enterostomy alone in such cases, where medical management has failed to produce results, is illogical. Excision of the ulcer alone or by partial gastrectomy is the desirable procedure

The fourth indication, a reasonable ground for the suspicion of carcinoma, concerns the lesion on the gastric side of the pyloric sphincter. Fortunately, X-ray evidence of improvement is more definite in gastric than in duodenal lesions. Fortunately, also, X-ray evidence of improvement in the gastric lesion with accurate medical management, is in our opinion fairly conclusive evidence of non-malignancy. Hence when such a lesion on the lesser curvature, the fundus, the posterior wall, or at the pylorus, fails to diminish in size within two to three weeks after the beginning of medical management, it may be suspected of being malignant and should become a surgical case. Up to the present, such X-ray evidence has, in our experience, always been substantiated by either the persistence of occult blood in the stools or the incomplete relief of symptoms. This test of malignancy has been of great value to our Clinic for three reasons: first, because it aids greatly in the early diagnosis of gastric carcinoma, secondly, because it protects from exploration and the operative risk of partial gastrectomy the patient with a non-malignant ulcer which previous to treatment had appeared suspicious, and thirdly, because subsequent to its use the reasonable suspicion of carcinoma justifies a radical procedure in a case where, with the lesion visible and palpable, the surgeon might still be in doubt as to the malignant nature of the lesion

Up to the time when this routine medical

treatment was adopted, exploration was of uncertain value. In those cases in which, with the abdomen opened, carcinoma was definitely obvious, the gross preoperative diagnostic data, commonly accepted, were already present. In many cases in which the preoperative diagnosis of gastric carcinoma could not be made because of insufficient data, then even with the abdomen opened and the lesion under direct vision and palpation, there was often great uncertainty as to whether the lesion was simply a chronic ulcer or an ulcer harboring malignancy. In such a situation the operation is really not an exploration, since one always resects at this time when in doubt. This has resulted in our hands in the past in the removal of ulcers suspected of malignancy, but postoperatively proven benign in patients who were thus denied the trial of medical treatment and, because of unfounded suspicion, prematurely subjected to the risk of surgery.

The fifth indication concerns the group of cases which in our three years' experience with systematic medical management is still a small one—namely, the group in which surgery has been done for failures with medical management. It is entirely possible that this group will increase in size as the years of follow up observation increase, and it is but fair to say that there must always be a group of individuals who will have recurrent symptoms and will require recurrent treatment.

As to the type of operation, if gastro-enterostomy has a mortality of two or three per cent and an incidence of gastro-jejunal ulcer of between three and thirty per cent (and I do not think that it is three, and in all probability it is not thirty), if, for instance, it is ten per cent, or even seven to eight per cent, and if in addition to this there are cases in which after gastro-enterostomy jejunal ulcer does not occur, but relief from pain or bleeding in the original ulcer is not obtained, then there are few of us who would wish to have this operation performed upon us when any other form of treatment or relief is available.

Now with regard to partial gastrectomy. There is no question but that it removes and quite positively controls acidity and eliminates later possibility of hemorrhage, perforation and malignant degeneration. If we could be certain that the ulcer were a pathological entity, we should be more ardent advocates of this procedure. Its disadvantages are (1) the possibility of recurrence of ulcer even with low or absent acid (such recurrences have occurred in our experience, and have been personally reported to us in the Clinics of Mayo, Schumacher and Moynihan), (2) the possible dangers of permanent anacidity with especial relation to the non-bactericidal gastric secre-

tion and pernicious anemia, (3) the high mortality.

In justice to the patient and to the surgeon, mortality rates must be regrouped and announced under several different headings. For example, in our experience, the less urgently indicated the partial gastrectomy is, as in ulcers on the anterior wall of the duodenum and gastric ulcers on the lesser curvature close to the pylorus, the easier it is to do and the lower its mortality. On the other hand, when this operation is applied to the old eroding ulcers which have involved the pancreas and must be cut away with marked oozing, leaving a duodenal stump which is difficult to close satisfactorily, or to ulcers high on the lesser curvature, or to the gastro-jejunal or jejunal ulcer with resection of a portion of the jejunal wall, the mortality rate undoubtedly rises.

Especially in gastro-jejunal ulcer should the mortality rate of partial gastrectomy be known, since the surgeon who employs gastro-enterostomy must have in mind the possible occurrence of gastro-jejunal ulcer and this possible secondary operative mortality. It is greatly to be desired, therefore, that mortality rates be re-grouped.

(1) for the high gastric ulcers, (2) for the eroding posterior wall ulcers with marked retroperitoneal induration, (3) for the gastro-jejunal ulcer, and (4) for the simple anterior wall duodenal ulcer with a free and mobile duodenum and the mobile lesser curvature ulcer close to the pylorus.

Jejunostomy, even though unsatisfactory in principle, in that the lesion is not removed and the causative factors probably still remain, must have a place in the surgical treatment of high gastric ulcers and gastro-jejunal and jejunal ulcers in patients who obviously will not stand subtotal gastric resection.

We must have in mind that the surgery of gastric and duodenal ulcer viewed as a whole is much like the medical treatment. They are probably both about equally unsatisfactory from the point of view of removal of basic pathology, and must be considered primarily not in terms of curativeness, but in terms of eventual mortality. For example, we prefer to treat uncomplicated duodenal ulcers medically through several recurrences of pain, and out of 165 peptic ulcers, 127 of which were duodenal and 38 were gastric, under our care during the past three years, we have seen no malignant degeneration during treatment and none has perforated.

It is, therefore, our duty to employ first, and with the utmost conscientiousness, the non-operative form of treatment with its almost negligible mortality, and to accept very seriously the responsibility for the thoroughness

with which this scheme of treatment is outlined and taught to the patient. We feel sure that just as Dr. Joslin at our hospital has been able to educate patients to manage their diabetes, so we are becoming able to educate patients to manage their ulcers.

Finally, when one approaches surgery only after the failure of a well planned and executed method of medical management in a patient who has been thoroughly taught its application, one may have a clear conscience, in that the patient must either accept the pain and discomfort of the persistently active ulcer, the possibility of death from obstruction, hemorrhage and malignancy, or the uncertainties of operation. We feel very strongly that surgery is not the primary method of treatment and that because of the recurrence of ulcer and because of the mortality rate of operation, it becomes the duty of the surgeon who accepts an ulcer case which has been a so-called "Medical failure" to be highly critical of that medical treatment, and before suggest-

ing surgery to re-submit such a patient to medical management of known thoroughness both in outline and in method of teaching to the patient. I speak from the position of a surgeon, but it is equally applicable to the medical man, that the uncritical acceptance of medical failures and the too ready application of surgery is not sound advice to the trusting patient.

In conclusion, we would reiterate that our answer to the interrogatory title of this paper, "When to Operate in Cases of Peptic Ulcer," is

- (1) In perforated ulcers,
- (2) In ulcers with unrelievable cicatricial obstructions,
- (3) In cases of recurrent severe hemorrhage,
- (4) In all cases where carcinoma can be reasonably suspected,
- (5) In cases of failure with known adequate medical management

## THE METABOLIC ACCOMPANIMENTS OF ACUTE INTESTINAL OBSTRUCTION

By HOMER L. NELMS, M.D., ALBANY, N. Y.

FROM a clinical standpoint intestinal obstruction can be divided into two great groups, namely the mechanical and the paralytic forms. In the mechanical form there is a definite interference with the fecal current as seen in strangulated hernias, kinks of gut caught by adhesions, volvulus and so forth. In this group the muscle tone is preserved for a time at least and nature endeavors to get rid of intestinal contents by setting up reverse peristalsis. These patients vomit large quantities of liquid material, greenish at first and later having a definite fecal odor. It is the fecal vomiting that often makes the diagnosis in this group of cases.

The paralytic form of intestinal obstruction is seen occasionally in the acute infections where there is loss of muscle tone and general asthenia. It follows abdominal section where there has been much handling of the intestines and is seen occasionally in general peritonitis. Here vomiting is not so apt to take place because the same mechanism that interferes with normal peristaltic action also prevents reverse peristalsis.

On physical examination these patients show a distended abdomen which is tympanic on percussion, this may extend well under the costal cage in the upper left hypocondrium and when present means a dilated stomach. The pulse and respiration vary according to the degree of toxemia present, late in the course the pulse is thready and weak and the respirations rapid and shallow. The temperature may be elevated, normal or subnormal.

In intestinal obstruction the examination of the blood gives us most significant findings and this holds true whether the obstruction be of the paralytic or the mechanical type. These patients all show a retention of nitrogenous products, within a few hours this retention occurs and continues to soar until the end comes or relief measures are instituted. The non-protein nitrogen frequently reaches 100 to 300 mg per 100 c.c. (25 to 35 is normal) and the urea nitrogen is retained in corresponding amounts. A non-nitrogen protein of 100 mg or more calls for a serious prognosis, there are cases in the literature that have recovered with higher retentions but these cases are rare. There may also be an increase in the creatinine content of the blood which may reach 8 to 10 mg per 100 c.c. of blood (normal 1.5 to 2.5 mg). This is not always present but when so indicates an increased endogenous metabolism.

The Mayos have shown that acute intestinal obstruction is always associated with a renal lesion as evidenced by the presence of albumin and casts in the urine but there is no scientific evidence to prove that this marked retention of nitrogenous products is primarily renal in origin, on the other hand there is much to indicate that its genesis is not renal but intestinal.

The carbon dioxide combining power of the blood plasma is increased together with a corresponding change in carbon dioxide tension of the alveolar air indicating that these patients among other things are suffering from an al-

kalosis The practical significance of this point is that they should not be given sodium bicarbonate by rectum as is often done. They already have an alkalosis, why add to it by giving more alkali?

The blood sugar findings are not especially significant, true there is often an increase in the blood sugar content and sugar often appears in the urine but how much of this is due to blood concentration and how much to altered sugar metabolism is difficult to state. The patients that come to early operation or go on to recovery are soon able to handle high carbohydrate diets so that it is believed the sugar function is not impaired to any great extent.

The total chlorides show a decrease in the blood plasma, frequently reaching a level of 200 mg or under (500 to 650 is normal). Just how this is brought about is not known at present but it is a clinical fact that the chlorides are low and patients improve when they are supplied. It has been suggested that the chlorides have a detoxifying action on the toxins that appear in this condition and the literature contains some experimental evidence to substantiate this fact.

The experimental laboratory has recently taught us much about the pathology of intestinal obstruction. The nearer the duodenum the obstruction the more rapid and more fatal is its course and this fact has led some to venture an explanation of the exact origin of the toxic substances that cause these marked metabolic disturbances. One theory is that there is a disturbance of protein metabolism and that these toxic bodies are really proteoses which for some reason are unable to be carried down to the amino-acid stage, another theory that has gained almost equal prominence is that the mucous membrane of the duodenum secretes a something that is absorbed and which has this marked effect on the individual. Be the cause what it may it is an accepted fact that intestinal obstruction is accompanied by marked metabolic disturbances and that the seriousness of the condition depends upon the extent of these metabolic changes that occur.

The treatment of acute intestinal obstruction does not only call for the relief of the obstruction but for the management of this altered metabolism. In the mechanical form early relief of the obstruction is the treatment par excellence, if this can be done before there is such a marked alteration in metabolism the prognosis is good. Dr. Finney of Baltimore once said that if he had an intestinal obstruction he would rather have the occasional operator operate on him early than the best surgeon in the world operate on him late. By early operation these metabolic complications can be avoided. An enterotomy high up is always indicated if the obstruction cannot be reached or if it has persisted for a number of hours. It is not bad surgery to do an enterotomy in the paralytic form of obstruction as this drains toxic material from the upper intestinal tract and assists in re-establishing a normal metabolic equilibrium.

Another procedure of almost equal importance is the so-called duodenal drainage, here a small specially devised tube is passed through the nose into the stomach and attached to a bottle at the side of the bed, the distal end of the tube must be lower than the stomach. Duodenal contents regurgitated into the stomach are thus siphoned off into the bottle. If the tube stops draining or becomes clogged a small syringe is attached and water gently forced through to clean it out. Even without an enterotomy patients will drain quarts and quarts by this method. One patient I recall drained 32 ounces the first hour the tube was in place. The tube is fastened with a piece of adhesive to the side of the face and is so small that it can remain in place for 48 to 72 hours with very little if any discomfort.

These patients are all dehydrated and require large quantities of water and as water cannot be given by mouth other routes must be utilized that is intravenously, subcutaneously and by rectum. For this purpose sodium chloride solution is by far the best. It helps replace the depleted chlorides of the blood and even by rectum is tolerated well. Some have considered sodium chloride solution the nearest drug approach we have to a specific in intestinal obstruction.

## ACTIVITIES OF THE SUFFOLK COUNTY MEDICAL SOCIETY\*

By WILLIAM H. ROSS, M D, BRENTWOOD, N Y

**W**HEN you asked me a few days ago to report at this meeting, the activities of Suffolk County Medical Society, I thought then that just a narrative of the work done would answer. It occurs to me now that I would like to say more.

We all will admit, I believe, that the final accomplishment of a medical program of work must be done in the smallest unit of medical organization, the distribution of the results of medical progress, whether curative or preventive, must originate in the ultimate organized unit. We are not so ready to admit, I believe, that the conception of activities starts there more often than in larger units of organization. The importance of a County Medical Society is often unappreciated. Just as in a government made up of states, certain functions belong to the government and certain rights remain with its component parts—practically true in all of its functions. Granting the great value of the county unit and recognizing its importance in the scheme of public health development, the county, for convenience and further development, pools its interests with a few accessible counties and conducts an organization known as the District Branch—a poor name, possibly, for branch means a part of something. It would be better called District Society. Up to this point, everybody has voice and vote in the organization, everything may be conducted on the town meeting plan where everything can be discussed until completely thrashed out. From here on organized medicine obviously takes a different form of government and administration.

In reality, the District Society is a complete organization made of several independent county societies and the best existing force to foster and guide the evolution in medicine, now going on faster than ever before. Final responsibility for the execution of a medical program lies with the County Society, inevitably, there is no exception. It is the ultimate unit and just as essential in any public health distribution plan, or advance in application of curative medicine as the individual doctor is in all features of health or medical welfare distribution to individuals. Just as we must not forget that the doctor sooner or later enters every home because sooner or later everyone gets sick, so we must not forget that the County Medical Society sooner or later must put over every medical program because there is no one else to assume the final responsibility.

As a background of the reaction of the Suffolk County Medical Society to its responsibilities, I want to speak of the effort to establish a tuberculosis hospital in 1913—fourteen years ago. The County Society bought a suitable site of 40 acres, conducted a campaign at a general election to

carry a referendum vote, won it by 2,000 majority against marked political opposition and then turned the land over to the County at cost. The Society has continuously worked for the hospital. It has helped to get appropriations aggregating \$350,000 for buildings, much more for maintenance, probably \$1,000,000 in all, and has always retained majority control of the Board of Managers.

In 1921 a Monthly News Letter was established and has continued ever since. It was almost the earliest in the State. It was established to unite the profession, to keep medical men posted on local medical needs, and to develop their sense of duty to the community. In that year we found that one mother in 172 died in childbirth in Suffolk County. This, later, led to plans to develop graduate education along practical lines.

It was also found that certain general practitioners were performing major operations for which they had no special training, and a free discussion has created sentiment against this.

The Society made an intensive survey of the four general hospitals of the county two years ago and published its report. The influence of this has led the county hospitals to improve their methods and facilities. During the coming year the survey will be remade for the purpose of bringing it up to date, incorporating the advances and making general suggestions toward advancing the standard of practice.

Two Pediatric Clinics of nine sessions each have been held in the county—the attendance of physicians average twenty.

The Society advocated a General Hospital for the indigent and an efficient one has been established at Yaphank.

Suffolk County stands high among the counties of the State in its tuberculosis work. The interest taken by its physicians in the anti-tuberculosis work is striking. Physicians are the leaders of the County Tuberculosis and Public Health Association. To illustrate its efficiency the death rate in the county per 100,000 persons was 120 in 1918. In 1925 it was 44.7 per 100,000 persons. This is the result of the application of the principle of examining all contact cases and keeping it up for at least five years.

Suffolk County Medical Society has endorsed by resolution the principle of accepting financial assistance from other sources, whether personal or lay organizations, and is in receipt of an income which it uses to finance its activities. In Suffolk we do not fear the Greeks "even though they come bearing gifts." The only condition is that this money shall be administered by the County Medical Society.

\* Read before the Second District Branch on January 7, 1927

In 1926 the News Letter, published by the Society since 1921, was expanded so as to represent the County Tuberculosis and Public Health Association, the Board of Child Welfare, the County Public Health Nurses' Association, the Red Cross, and all other medical, health and welfare organizations in the County, for the purpose of furnishing news information—a sort of clearing house—so as to prevent duplication of effort, to limit waste, and to increase efficiency. This effort is working well and is entirely under the active constructive leadership of the County Medical Society. This conception of organization is new in the State of New York. We are succeeding in winning cooperation of all the lay health organizations in the County and creating a greater organized health force than I am aware of having been attempted in any other county.

The News Letter is now sent to doctors, lawyers, clergymen, political leaders and to interested organizations and laymen. We send out 1,000 copies now and expect it will be 2,000 before the year is over. We are financing it, paying our bills as we go, and providing for expansion.

One of our present major activities is creating public sentiment by an active campaign in writing and speaking, looking toward the establishment of a County Health Department.

Growing experience in public health work in Suffolk County leads to the conclusion that little or no further real advance or likelihood of a permanent uplift in the promotion of health and prevention of disease will occur unless there is a better administrative organization. The Medical Society of Suffolk expects to bring about this feature of organization this year and give to the county the same possible efficiency in health matters now given to New York or Syracuse or Buffalo.

The Society has taken an active interest in promoting a wholesome milk supply and has stimulated one hospital—the Southside—to equip its laboratory to do bacterial counts of milk samples for little or no compensation if needed.

Suffolk County has, of course, endorsed toxin-antitoxin and the campaign is going on. It lags and flourishes in spots—no better and no worse than elsewhere.

We are about to establish a nose and throat clinic at the Southside Hospital modeled on the

plan of the Cornell Clinic and adapted to local needs.

Some random studies show that there are probably upwards of ten thousand children in Suffolk County suffering from affection of the throat and requiring treatment of some kind.

The correspondence courses in graduate education authorized at the last annual meeting of the Suffolk County Medical Society is arousing interest. Five experiments are now under way to develop such courses.

Physical health examinations are being promoted. Its public health and legislative committee are stimulated to greater effort. With all these things, however, we have one great and fundamental activity—the promotion of good will and the spirit of service—so as to make a united force of the entire membership. We have no factions. We have good leaders and good followers.

When we wanted support for legislation last year every doctor but three of the 150 in the entire county, when requested, responded by writing letters to our members of the legislature. Our plans have always been reasonable, possible and definite. Some of our undertakings are complete—others have not yet ripened into maturity. We have nevertheless gained a perspective that no one could have gained except by a more or less similar period of observation and study and experience.

I wish to quote the following from the inaugural address of the incoming president of the Suffolk County Medical Society this year, Dr Frank Overton:

"Fortunate is the County Society which can develop a consistent policy from year to year, and which has an interested personnel to carry on its work. Officers may come and go, but those of Suffolk County Medical Society continue active in the Society long after their terms expire. Office holding is merely a preparatory training for sustained interest in the affairs of the Society."

The Suffolk County Medical Society over a period of twenty years has fulfilled its avowed purposes to a very large degree. Its record for initiation and accomplishment has done much for the economic uplift of its members, for public health, and for the advancement of the standards of practice—both in curative and preventive medicine.

## ACTIVITIES OF THE MEDICAL SOCIETY OF THE COUNTY OF QUEENS\*

By EDWARD A FLEMMING, M D, RICHMOND HILL, N Y

THE activities of the Medical Society of the County of Queens during 1926 were many and varied. We deem it sufficient for this report to briefly refer to some of the major or more important activities of last year which were attempted or consummated.

In the field of public health early in 1926 the Medical Society of the County of Queens advocated a County Hospital. We found that our population had grown to a variously estimated figure between 644,000 and 713,000 people. We knew our acreage area was estimated at over 69,000 acres. We knew in point of size, we were the largest of the five boroughs of this great city of New York, and yet we were without a public hospital. A unanimous resolution was passed in one of our meetings, early in the Spring calling our attention to our great need in this respect and delegating our Public Health Committee to look into the matter. A report from this committee showed a widespread desire for such an institution. Ardent efforts were made and are still being pressed to get such an institution started. We have reason to believe that this movement properly directed can be carried to a successful conclusion.

Another activity of our Public Health Committee was to stage a drive among our County Society members to stimulate them to not only advocate but to actually have an annual periodic health examination. Twenty-two per cent of our members responded. We hope to push this matter still further in 1927, inducing a larger population to participate. Then we hope to stage a county-wide campaign for annual periodic health examinations. This campaign to include everybody from children to old age, male or female.

We believe periodic health examination is a salable product, we purpose to sell it to the laity of our county by whatever means we can. In this movement we will combine chambers of commerce, public health associations and even the Board of Health itself. Also movie theatres and borough newspapers, if we can secure the necessary funds, always an acute subject in Queens.

In the field of graduate education we offered to physicians of the county 28 clinical courses. Twenty-three and one-half per cent of our county membership availed themselves of these courses. Our Committee on Graduate Education offered 33 Friday afternoon talks. These talks were attended by over 1,200 men. In other words graduate education was carried to over 1,200 practitioners by our Friday afternoon talks. Out of more than \$770 contributed

by the Queensboro Health and Tuberculosis Association for use in graduate education and due to the fees collected from our courses we are going into 1927 with about \$100 on the credit side of the ledger for use in graduate education. That is, graduate education in Queens has not really taken one dollar out of our County Society treasury.

We believe graduate education has been a great force for good in our County Society. It has been a leveller of inter-county walls. It has been the solder so to speak, tending to establish contact between members in distant parts of the borough. It has been a melting pot tending to fuse and weld into one our County Society. Men no longer speak of being Long Island City or Rockaway men. They are all proud to be recognized as Queens County men. This is one debt which the men of Queens County are glad to publicly acknowledge and give the credit where credit is due—to graduate education.

Our Membership Committee must be given mention in this report. Through its efforts our roster has been increased 21½ per cent in 1926. These figures speak for themselves. The State Medical Directory of 1926 lists the number of physicians in the Borough of Queens as 596. Excluding undesirables and those who for some reason or another cannot qualify, the best possible number we could have upon our county books would be 500, in the Borough of Queens. It is at this goal we are aiming. The slogan of our 1927 Membership Committee will be,

**"EVERY QUALIFIED PRACTITIONER OF MEDICINE IN QUEENS A MEMBER OF HIS COUNTY SOCIETY"**

One of the most pleasing things of officers of the Medical Society of the County of Queens which occurred during the year of 1926 was the increased interest and increased attendance at our stated meetings. Our attendance at our stated meetings in 1926 was increased 13 per cent over our attendance at the stated meetings in 1925. The increased interest cannot be expressed mathematically.

We believe our society is in better shape financially and numerically, and we are sure it is stronger in enthusiasm and unity, than it has ever been before. We are looking forward into 1927 full of hope.

We stand ready to take our place with our neighboring fellows of the State Society, and to do our part in an energetic and forceful manner, in any work which organized medicine has to do.

## CONCERTED ACTION IN PUBLIC HEALTH

Health is an adjustment to one's environment. A primitive end of adjustment is sufficient to produce a superb body in central Africa where nature provides food already prepared, and clothing and housing scarcely enter into the thoughts of the people.

A highly specialized adjustment is necessary everywhere in New York State if the citizens are to be healthy and vigorous. In addition to the medical profession, there must be departments of health to secure coordinated action against threatening diseases, and there must be

lay organizations to influence governmental agencies in health relations and to educate the people regarding health matters.

Medical societies throughout New York State have come to cordial agreements with boards of health in regard to their peculiar fields of effort. The medical societies are developing equally co-operative relations with lay health organizations, as is evidenced by the actions of the Cattaraugus County Medical Society (see page 82) and the appointment of a committee on Public Relations by the Council (see page 81).

## THE PUBLIC RELATIONS COMMITTEE

Interest in the practice of preventive medicine permeates all classes of society and all countries of the globe. Statisticians have shown that to it may be attributed the marked increase in the expectancy of life noted in the last generation. Governments have proven that some territories, particularly in the tropics—heretofore uninhabitable because of the ravages of disease—may be made comparatively safe to human beings through careful observance of well established practices of sanitation and public health.

Probably the most objectionable manifestation of the widespread cooperative interest in preventive practices among the public is the success which the most nonsensical quackery meets which advertises to cure or prevent any and all pains and aches. Until within the last few years, the only agencies to give public expression to methods of prevention and make concerted efforts to incorporate them into the habits of daily life, were the public health agencies, governmental and voluntary. Physicians, as a rule, were skeptical of the benefits that would be derived from practicing medicine by broadcasting methods, and feared they were being driven to state medicine. Open hostility to public health activities has been shown at times, but recently a more cooperative spirit has been developing. Dr. Luckett in a paper read before the section on preventive medicine at the A. M. A. meeting in Dallas, groups the reasons for this antagonism under the following heads: "(a) Ignorance of public health practice on the part of the physicians, (b) Improper

methods and policies on the part of health workers, (c) Mercenary motives of some influential physicians, and (d) An often unconscious suspicion of all governmental activities and of those who promote them."

The practice of preventive medicine and public health activity are not synonymous, they have some common ground, but each extends from that point into a field that should be more or less its own. The average physician is not a trained sanitarian and has repeatedly shown his inadequacy in promoting educational and informational activities and, on the other hand, the mobilization of the public against the inroads of an epidemic or unhealthful practice is very different from the scientific advice to be given the individual in regard to his own body and habits. This distinction is being recognized by all health workers as is evidenced by the type of campaign being waged today in favor of periodic medical examinations of the apparently well and by the effective cooperation of physicians and lay organizations in the anti-diphtheria activities.

Through the Public Relations Committee, recently authorized by the Council the State Society hopes to assure the public of the willingness and intention of it and its component County Societies to cooperate with all health departments and voluntary groups whose activities enter the field of health, in producing programs that will guarantee the greatest benefit from all public health and preventive medicine activities.

GEORGE M. FISHER.

## STATE AID IN HEALTH WORK

State medicine was first proposed as a method of taking medical service to that great group of people who could neither command the services of expert physicians in cases of sickness, nor could adjust their lives to a wholesome manner of living. The insinuation was that lack of interest was the reason that physicians failed to afford medical service to the poor, and the threat was made that the state would provide the medical service if the physicians would not do so.

A thorough trial of state or socialistic medicine was made in Europe, and it demonstrated the facts that the medical service was poor, and that the people were dissatisfied with it. The reasons for the mutual dissatisfaction are plain. No one can go into the market and buy disinterested medical service, such as that given by family physicians to whom night is as day and storm as fair weather when one of their patients is in distress. Neither will the people cooperate or lift their hands to help themselves when medi-

cal service is presented to them on a silver platter.

Everything worth while comes as the result of effort. Medical service that is of value is that which the physician renders with a wholehearted devotion to duty, and its result will depend on the efforts of the family to follow his directions at the cost of time and effort and money. All these elements were lacking in state medicine.

However, there has been a universal development of the idea that the state has an important place in public health work. Community responsibility is recognized in problems connected with industry, poverty, crime, education, and all other questions affecting individuals. Hospitals, health departments, and public health nurses are all necessary in doing public health work in a community. But all these means of work cost money, and money is unequally distributed among both individuals and communities.

Shall the richer communities provide their own health workers, while the poorer districts go with-

out modern medical service? The modern answer is that each community shall contribute according to its means. Now the means at the command of any community are two-fold. First, physical, which actually resolve themselves into the financial, and second, spiritual, which consist of a willingness to put forth such efforts as are reasonably possible.

All communities are on an equality in regard to their spiritual means, for the poor community may try as hard as the rich one.

Out of this conception of local self-help has risen the modern idea of state aid that is taking the place of state medicine. The New York plan of state aid in public health is that the state shall bear half the expenses of certain health activities which a village, town, or county shall undertake of its own accord. Public health

nursing, child welfare, local laboratories, and county health officers are some of the projects in which the State of New York is already giving aid to local units.

The plan of state aid in public health lines received the hearty approval of Governor Smith in his Annual Message (see page 89). Physicians may now feel encouraged to undertake the promotion of public health work along lines which would have been impracticable a few years ago. Moreover, the people themselves, as represented by lay health organizations, are firm supporters of the plan of state aid of public health work.

Physicians feel encouraged to do their conscientious share of public health work, since there is an increasing assurance that their efforts will be appreciated and their advice followed.

---

### THE CHIROPRACTIC HEARING

The investigation into the merits of chiropractic now being conducted by a joint committee of the Senate and Assembly may have important bearings on future legislation. The chiropractors have come before the Legislature every year for over ten years, and have produced much evidence in favor of their official recognition. Last Spring the Legislature granted their request for an opportunity to present their claims to an investigating committee with the understanding that the committee would suggest whatever legislation may be necessary for the public interest.

Two hearings have already been held, and other sessions are promised for the near future. The chiropractors have been treated courteously, and fairly, and have been allowed entire freedom in the presentation of their arguments. What these arguments are may be seen by referring to the reports on page 85 of this Journal.

So far the chiropractors have given no hint of discord in their ranks. The evidence has been that regarding the pure chiropractic practice advocated by B. J. Palmer, the founder of the cult. But in 1924 and 1925 this Journal

printed several articles quoting B. J. Palmer's criticisms of the actions of a large proportion of chiropractors who practice many manipulations which have no relation whatever to chiropractic.

The question will surely arise, "What is chiropractic?" The American Medical Association answers that question in its Bulletin for April, 1925, by quoting the definition of chiropractic taken from the laws of twenty-seven states that have permitted the licensing of chiropractors. There is no consistency in the definitions. A chiropractor in Kansas may adjust by hand "any displaced tissue of any kind or nature," while in Arizona he may adjust only the spinal column, and between the two extremes are all grades of permissions.

Physicians will be heard in rebuttal of the claims of the chiropractors, but besides those who will appear at the hearings, every physician can prepare himself to speak to his patients and friends about chiropractic and explain the grounds of medical practice as contrasted with those of the cultists.

---

### COUNTY HEALTH OFFICERS

While doctors are individualists, they also recognize the necessity of group action. A doctor in his ordinary practice acts as an individual who deals with a patient, also an individual, who has, let us say, typhoid fever. The doctor's responsibility extends to others besides the patient, for it is his duty to protect the other members of the family, and also the neighbors from catching the disease. But suppose the patient caught the disease from a public water supply, the duty

of prevention then passes to the governmental officers of the municipality, and back of them, to the voters and taxpayers who put the officials in their places. Thus there is clearly a direct responsibility on the trinity of public health forces—the physicians, the health officials and the lay organizations, such as tuberculosis committees, chambers of commerce, and civic improvement societies. The health responsibility of laymen and governmental officials is now gen-

erally recognized, but the establishment of machinery to secure community action, either official or voluntary, is slow in developing. But the movement has advanced sufficiently to indicate the general lines along which the machinery will be planned.

Physicians and lay health workers have reached an agreement that the county health plan is the one adapted to rural and semiurban communities. The old fashioned system of a local health officer for each village and town is well adapted for dealing with individual cases, such as a scarlet fever patient, or a polluted private well. But it is not adapted to conditions whose control require group action. An ordinary dairyman, for example, supplies people in two or three municipalities, and the inspection of his plant and the bacteriological examination of his prod-

uct must be done by each health office district if a real control is to be exercised. A dairyman whose milk is condemned in one village may sell his product in the next village where the oversight is lax. A county unit has been proved to be about the right size to secure efficient public health work. The plan is endorsed by Governor Alfred E. Smith in his Annual Message, it is advocated by the officers of the Medical Society of the State of New York, and it is being actively promoted by several county medical societies of New York State. The principle is that the present system of local health officers shall be retained in order to deal with individual cases, and that a county health officer shall deal with those conditions which require concerted group action.

## LOOKING BACKWARD

### THIS JOURNAL TWENTY-FIVE YEARS AGO

*Restrictions on Consumptives*—A quarter century ago people were becoming aware of the contagiousness of consumption, and were demanding stringent measures of quarantine against those who had the disease. This Journal for January 1902 considers the problem in an editorial which reads:

"Popular sentiment is generally hard to awaken, and very likely when it has been aroused to swing to the opposite extreme and be unduly sensitive and unreasonable.

"Nothing in medical literature better illustrates this than the popular attitude toward tuberculosis. It is only a short time since the disbelief in the communicability of tuberculosis was almost universal. Now the public, with its half knowledge, is firmly convinced that the disease is not only communicable but contagious, and we must expect to see much unnecessary hardship inflicted on this diseased and defenseless class.

"Because of a declaration by the Surgeon-General of the Marine Hospital Service, that pulmonary tuberculosis was a dangerous, contagious disease, the Superintendent of Immigration has issued an order that in future all immigrants with this disease must be turned back from our ports, whether the aliens be first or second class passengers or steerage.

"More recently the Board of Health of Liberty, Sullivan County, has enacted an ordinance providing that no building situated within the limits of the village shall be used as a sanitarium for

the reception of patients afflicted with consumption. A first violation of the offense is punishable by a fine of \$50, and for a subsequent violation there is to be a penalty in the discretion of the board, not to exceed \$100.

"This means that Liberty, which was rapidly becoming famous as a resort for consumptives, will not be allowed to receive them any more. Hotels for their reception, costing thousands of dollars, have been built, and in winter they used to flock there in great numbers. Every hotel in Liberty, except one, catered to their patronage."

The editor had his doubts about the wisdom of segregation of consumptives in public sanatoria. Experience has shown that the fears expressed in the following quotation were not justified.

"There is a tendency among all sorts of people to look to the powers that be for help in the emergencies they cannot meet themselves, but as a rule it is only justified in extreme cases. The communal care of the sick, the insane and the criminal has always been and probably always will be far from perfect. The power that takes the helpless and infirm away from the natural protection of relatives will always at times be abused.

"We should hesitate long before turning the consumptive over to the same tender care. The powers which can see revenue in sources as far apart as the prostitute and the milkman are not likely to be oblivious to the revenue of the sick who want to stay at home."

# MEDICAL PROGRESS

**The Cancer Problem**—In an article in the *Lancet* of November 13, 1926, ccc1, 5385, W E Gye describes further experiments with the Rous tumor. He recalls that in a former article it was shown that the filterability of the Rous tumor extract is not certain, all that can be said is that generally a filtrate of a tumor is active, but often it is quite inert. Gye has confirmed the work of Rous and Murphy, who found that tumor extracts are always robbed of their activity by exposure to a temperature of 55°C for 15 minutes. His experimental work indicates that the agent which is destroyed by heat is variable in quantity (or quality) in filtrates from different tumors. Another group of experiments demonstrates the fact that chloroform and acriflavine inactivate the Rous tumor extract, and that the element destroyed by heat is not the same as that destroyed by acriflavine. Furthermore, the two inactive fluids, when mixed together, acquire the power of inducing tumor formation. From the experimental evidence Gye feels satisfied that the production of a tumor with cell-free filtrate depends upon the conjoint action of two elements in the filtrate, one rendered inactive by acriflavine or other antiseptic, and the other inactivated by heat. It is only because of the activity of the latter element that the presence of a virus can be shown in the Rous sarcoma. The agent which is destroyed by antiseptics (the virus) is unable alone to induce sarcoma formation, it is, he says, a living filterable microbe and, in Gye's opinion, is the cause of new growths. The evidence that the agent is a microbe lies in the fact that it can be killed by antiseptics and can be cultivated. It is further shown that there is an agent contained in tumors of diverse origin and diverse structure which has the supremely important property of reactivating an extract of Rous sarcoma which has been inactivated by means of an antiseptic. Gye claims that these new facts are compatible with the known facts of cancer structure and behavior.

**The Clinical Effects of Lead in the Treatment of Malignant Disease.**—L. Cunningham, writing in the *British Medical Journal*, November 20, 1926, 3437, stresses the difficulties and dangers attendant upon the lead treatment of malignant disease. The obvious contraindications are gross pathological lesions of one or more organs of the body, serious cachexia, and the idiosyncrasy of the individual to lead. Before administering lead the important organs of the body should be carefully examined and a

complete analysis of the blood and urine should be made, with radiological studies where these are likely to be of assistance. Full blood counts should be made, with blood film examination for stippling of the red cells. This has proved of great value in indicating both the dose of lead that should be administered at any given time and the interval which should be allowed before a further dose is given. When there is reason to suspect liver involvement, a levulose test is made. The author outlines the various toxic effects of lead upon the blood-forming organs, the gastroenteric tract, the kidneys, the liver, and the central nervous system. All types of anemia are encountered, from grave secondary anemia to aplastic pernicious anemia. In the usual type the reduction in hemoglobin is more marked than the reduction in red blood corpuscles. Other changes noted have been polychromasia, anisocytosis, poikilocytosis, and the appearance of abnormal forms. In several of the author's cases the blood destruction has been so severe as to call for transfusion. Recovery from the anemia following large doses of lead is rapid, while after the administration of small doses continued over a long period it may be very protracted. The variations of the white blood corpuscles are not as characteristic as those of the red blood cells, leucocytosis, relative lymphocytosis, slight eosinophilia, and leucopenia have been observed. The kidneys are often involved early. Albuminuria has been recorded in 25 per cent of the cases. Lead influences the bile-producing mechanism just like phosphorus, arsenureted hydrogen, and toluylene-diamine. Nearly all the serious toxic effects of lead may be avoided. During the treatment the kidneys should be relieved by a light diet, a liberal fluid intake, and restriction of protein. If vomiting is associated with ketosis, glucose and insulin should be given. The intravenous injection of a solution of calcium chloride (5 per cent) appears to be beneficial by rendering the lead salts insoluble. The dosage of lead, provided there are no untoward effects, is two doses of 20 c c and two of 15 c c of the 0.5 per cent preparation, at ten-day intervals. The patient is then allowed one month's rest, when the treatment is resumed, using smaller doses (10 c c) at varying intervals, until 120 c c of the solution, or 0.6 gram of lead, has been given. Where a tumor is of slow growth, even smaller doses may be given, thus avoiding acute toxic effects. Cunningham, at the end of the first five year period, reports that of 247 cancer patients seen, of which 227

received treatment, 50 were benefited, and are either leading normal lives (9), or the disease is arrested (10), or it is believed to be cured (31) Surgery and the x-rays have been combined in the treatment of these patients There is reason to hope that a better preparation of lead will be found in the near future

**Combination of the Specific and Malarial Treatments of Syphilis**—Professor G Scherber discusses this subject at length and from several quite distinct angles By specific treatment he refers to the use of the spirillicides and especially of arsphenamine and bismuth Malarial virus itself has of course been claimed as a specific remedy, but is better regarded as the most successful of the pyretogenic substances and one which in theory should be able to antagonize any microorganism which has a low heat stability In the early tests of malarial virus it has been necessary to apply it alone, using the spirillicides either before or after, or both before and after The genesis of fever can have other than salutary effects, and the author recalls a case in which a typhoid bacillus harbored an acute reappearance of the disease in connection with an outbreak of variola which mobilized an old focus of bacilli in the gall-bladder, spleen, or elsewhere Hence the thought of combining the administration of a spirillicide with the malarial inoculation Scherber does not seem to stress the presence of metasyphilis in connection with this idea, the chief aim being apparently to render the blood and cerebrospinal fluid negative to tests The malarial treatment may produce this result but we do not yet know whether it will prove to be permanent In tests of the malarial treatment of fresh syphilis, the author was unable to obtain even a negative blood Wassermann, but after the patients, three in number, had received the usual spirillicide treatment they responded to the same with unusual promptness and thoroughness The author concludes that the malarial virus acts on latent foci of syphilis in a quasi-specific manner as a synergist to the general sterilization accomplished by the arsphenamine and bismuth The combined treatment is therefore indicated whenever there are old foci of the disease anywhere in the body—*Wiener klinische Wochenschrift*, November 11, 1926

**Immunity of Paretics to Framboesia.**—F Jahnel and J Lange have already called attention to the apparent immunity of metasyphilitic patients to framboesia inoculations, which were not made in the interest of scientific curiosity but in the hope of stimulating the formation of immune bodies The framboesia virus had been obtained from Major Nichols of the United States and had been

passed through the rabbit before inoculation Since this episode the authors have obtained other virus through the courtesy of Drs Louise Pearce and Howard Fox of New York, and have repeated their original experiments with the same negative result The material of the second series comprised 8 paretics and 1 tabetic A patient with ordinary lues cerebri developed doubtful papules at the inoculation site which soon vanished, biopsy showed the absence of spirochetes These negative experiments must be grouped with some of the results of others in crossed immunity to syphilis and framboesia in rabbits It would be natural to claim in hostile criticism that passage of the virus through the rabbit causes it to lose its specific character, but unfortunately for such a view the authors have control material in non-syphilitics who reacted positively to framboesia inoculation Details are not submitted in full, but the authors have tested therapeutic inoculation on a patient with multiple sclerosis, but are not yet prepared to report on the subject The authors will continue their efforts on metasyphilitic patients and are hoping to obtain framboesia virus from the East Indies before coming to a final conclusion In the meantime the question of the identity or close relationship of syphilis and framboesia is still far from settled, although at one time the evidence of dualism seemed almost complete—*Klinische Wochenschrift*, November 5, 1926

**Treatment of Catarrhal Jaundice with Insulin**—H Schneider refers in the *Wiener klinische Wochenschrift*, October 28, 1926, to the discovery by Richter that insulin and glucose given jointly appear to hold back the fatal termination in icterus gravis, and this naturally suggested the possibility of the value of this treatment in the milder forms of jaundice, especially catarrhal jaundice which has become chronic The affection should normally pass off in from 3 to 6 weeks and it occurred to the author to determine whether this period could be shortened He has had opportunity of treating a number of these acute cases, giving 5 units two to three times daily, and has been surprised to note how rapidly the jaundice clears up Its average duration in more than a dozen cases has been three weeks In addition to insulin the patients were on a strict carbohydrate diet and received enemas of glucose solution and at times glucose intravenously In order to understand these results we must bear in mind that, since the dictum of Eppinger, catarrhal jaundice has been recognized as a mild form of hepatitis which sometimes becomes chronic and may pass into acute yellow atrophy This does not mean that there is not a simple obstructive jaundice of a transitory character, but

that under the present conditions any jaundice must be thought of as a possible hepatitis. At any rate protein should never be given to these patients on account of the possible formation of toxic end-products and in general of interference with the glycogenic function of the liver. Glucose exerts a detoxicating action and the galactose and levulose used in testing hepatic sufficiency also are of use therapeutically, favoring glycogen storage. An added reason for withholding any excess of protein in the diet is found in the fact that the pancreatic external secretion is often defective in hepatic cases.

**Expulsion of Renal Calculi by Means of Hypophysis Extract.**—H. Feilchenfeld contributes to the *Deutsche medizinische Wochenschrift*, of October 29, 1926, a very brief note on this subject which is practically a short case report. It has quite recently been announced by Kalk and Schondübe that extract of the posterior lobe of the hypophysis can cause forcible contractions of the ureter, the authors suggesting its trial in renal colic. They also have reported three cases of the successful use of the extract. The present author implies that his own case may have a claim to priority although it was not placed on record at the time, possibly because the result was not entirely satisfactory. The patient was a woman who had been under treatment for renal lithiasis before, but who presented herself last February with increasing cystopyelitis and a history of repeated acute crises of pain. Stone shadows had already been recognized when the patient was previously under treatment. The pyelitis was first treated and an injection of pituitary extract was followed by severe renal colic without expulsion of the stone. A second ampoule injected brought about a second crisis of pain, again without passage. The rest treatment was now substituted and a control radiogram showed a stone adherent in the pelvis. Since then there has been no active treatment and no more colic. The author demonstrated that hypophysis extract provokes specific contractions of the ureter and suggests that a movable stone in that canal would probably have been expelled.

**Non-Tropical Sprue.**—T. E. S. Thaysen of Copenhagen discusses tropical sprue as seen in patients home from the tropics, which is recognized as one of the most dreaded diseases of these regions, with its extreme emaciation, weakness, anemia, diarrhea, and stomatitis. Recently great surprise has been occasioned by the appearance of a few sporadic cases in residents of Northern Europe and America who have never left home. The author saw one such case in Copenhagen in 1922 and found that his was really the fifth that had appeared in

that city, all in native Danes who had never traveled. These cases may masquerade as fatty diarrhea, which apparently may be the sole symptom. In other cases the coexistence of stomatitis with anemia has probably suggested the diagnosis of pernicious anemia. The sprue described by Thin in 1897 under the name psilosis has been identified by some as pernicious anemia. In 6 of the 8 cases in which blood examinations have been made in non-tropical sprue, reported by different observers, the blood counts have been those of Biermer's anemia. It is becoming increasingly probable that the latter affection is only a syndrome, a collection of quite different diseases, which bring about anemia. So that if this is true it will not help us any to say that this form of sprue is only pernicious anemia. In the author's material there was no severe clinical anemia. The diarrhea often appears to be of the pancreatogenic type, but this occurs under various circumstances—for example in diabetes—a condition which may have to be excluded in the differential diagnosis. Absolutely nothing is known of the etiology of non-tropical sprue. No treatment is of any benefit save expectant and symptomatic remedies, the disease is more obstinate than tropical sprue which is amenable to treatment with removal from the tropics.—*Klinische Wochenschrift*, November 12, 1926.

**Prevention of Coryza.**—Andrew S. J. McNeil, writing in the *British Medical Journal* of November 6, 1926, 3435, states that for the last fourteen years he has advocated the use of soap as an almost certain preventive of "colds," if used regularly, it is also the most valuable part of the treatment of an established "cold." As a preventive, the patient is instructed to get a rather thicker soap lather than usual on his hands, and to smear it over the face in the usual way, rubbing it over the nostrils half a dozen times or so, without attempting to push it into the nostrils or to sniff it, then several handfuls of warm water are thrown against the openings of the nostrils, again without sniffing. Then the nose is blown, one side at a time, when it will be found that quite a quantity of mucus, inspissated and fresh, mixed with dust and debris, comes away. When a person already has become infected, the above method, along with a few tablets of acetyl-salicylic acid taken at intervals after food, will soon clear up the generalities of a cold in a normal nose. If there is a sore throat a few formalin tablets will be a great help. The soap method does away with the certainty of microbes being carried into the upper regions and saves the delicate nasal mucosa from the insult of coming in contact with "foreign" antiseptics, in douches,

sprays, and sniffing from the hand. The soap lather stimulates the ciliated and globular nasal epithelium, and causes a flow of mucus from above downward. The soap should be a good toilet soap, not one containing free alkali. This very simple measure should be taught to children and should become a routine in the prevention of colds, which in the aggregate inflict an immense loss on the country. The writer does not use anti-cold vaccines, as he thinks the toxin of *M. catarrhalis* is apt to weaken the myocardium.

**Ischemic Contracture**—Paul W. Jepson (*Annals of Surgery*, December, 1926, lxxxiv 6) describes certain experiments in dogs which reproduced the mechanism of this condition as seen in man. After the application of an Es-march bandage to the right pelvic limb for 1 1/2 to 4 hours the deformity manifested itself by a *man-en-griffe* which disappeared in the course of three or four hours. When the ligature remained for a longer period, the deformity persisted for three or four days. Ligation of the femoral vein over the right thigh also produced the deformity. A combination of the two procedures produced typical ischemic contracture similar to that in man. The contracture may be explained by a number of factors, most important of which are impairment of the venous flow, extravasation of blood and serum with swelling of the tissues and consequent pressure on the blood vessels and nerves in the involved area. As the condition progresses, due to the diminished blood supply, the flexor muscles begin to atrophy and the tendons become matted together. If the intrinsic pressure is relieved by early drainage of the hematoma, the patient will usually recover.

**The Treatment of Infection of the Nasal Accessory Sinuses**—G. Seccombe Hett, writing in the *Lancet*, November 6, 1926, ccxi, 5384, says that in patients giving a history of severe head cold, it is almost axiomatic that unilateral pain in the face, temple or brow indicates extension of the inflammation of the nasal cavities into one or other of the nasal accessory sinuses. Drainage of the affected sinus should be obtained by medical means if possible. The patient should be put to bed, the bowels should be kept well open, and if there is pyrexia the ordinary medicinal treatment for this symptom should be given. Every four hours a steam inhalation should be given. As a basis, Friar's balsam is a useful inhalant, 1 dram to a pint of boiling water. In antral infection the patient should lie with the head over the side of the bed on the opposite side to the sinusitis, and then sit up, close one nostril and gently blow the secretion from the other. Between the steam inhalations the

patient should use in a nebulizer the following or a similar prescription: Menthol 15 grains, cocaine 4 grains, glycerin 3 drams, tincture of benzoin (simplex) 1 ounce. If there is obstruction of the ostium maxillare or infundibulum, relief is often obtained by placing a pledget of cotton, soaked in 10 per cent cocaine and squeezed until only damp, between the middle turbinal and the septum. After the pledget is removed a second one is placed under the middle turbinal thus opening the outlets from the antrum, frontal sinus, and ethmoid cells. If the antrum does not drain despite these methods, puncture through the inferior meatus may be made to facilitate lavage with an antiseptic alkaline lotion, such as glycothymol, B.P.C., to which has been added one dram of tincture of iodine to a pint of lotion. Radiant heat baths for the head, as well as sunlight, have given good results. In acute antritis it may be necessary to open the antrum for drainage, but radical operation should not be performed at this time. In chronic antritis the radical operation should be performed during a quiescent period.

**Treatment of Perineal Pruritus**—Dr P. Gallois employs this term to include both genital and anal pruritus because of the tendency of the two to coexist in the same subject. Sometimes there is difficulty in deciding which of the regions is primarily involved. Moreover, even when quite distinct, the two local forms appear to have a common origin and yield to the same treatment. If the origin is not the same it may be similar. Either form may be due to some constitutional state, such as nephritis or diabetes, while some source of irritation in the vagina and rectum respectively may set up pruritus of the vulva or anus. Eczema may appear primarily and be attended with symptomatic pruritus, and conversely a scratch eczema may develop on a primary pruritus, and we may see a vicious circle in operation, so that it may be very difficult to decide as to the nature of the original mischief. The author mentions a special form due to douching of the vagina or rectum. The irritant may not be the water but rather some of the substances in solution, chiefly alkalies, including soap. The itching ceases with the abandonment of the practice of douching. Treatment must consist largely in recognition and removal of the cause. Under symptomatic treatment the author mentions many substances in use but gives the preference to ointments and oily preparations, having learned to distrust lotions. For a menstruum he likes olive oil or equal parts of this and glycerin and his antipruritic drugs comprise menthol, chloroform, and sublimate in weak concentration.—*Journal de Médecine de Paris*, November 1, 1926.

# LEGAL

By LLOYD PAUL STRYKER, Esq  
Counsel, Medical Society of the State of New York

## LET US FACE THE NEW YEAR WITH UNITY AND WITH CONCORD

In our editorial printed in the State JOURNAL for January first, your counsel took occasion to analyze and to discuss the recent decision of the Supreme Court of the United States, in the case of Lambert against Yellowley, in which, as will be recalled, our highest tribunal by a vote of five to four, decided that Congress has the right to limit the amount of vinous or spirituous liquors which a physician may prescribe for his patient

Your counsel called attention to the fact that one of the principal reasons which actuated the Supreme Court in reaching its decision was that Congress had a right to decide this question because there was a difference of opinion among the members of the medical profession as to the therapeutic value of vinous and spirituous liquors. With great emphasis the Supreme Court referred to the fact that high medical authority was "in conflict on this question"

Your counsel, of course, appreciates that on so delicate and troublesome a question as the proper medicine to be given a patient and the therapeutic value of this or that remedy it would be difficult entirely to avoid conflict, nevertheless he would like to take this occasion to stress the fact that owing to this conflict a decision was rendered which materially limits and restricts the judgment of a physician as to the proper remedy to be prescribed by him for his patient

In his travels throughout the state appearing constantly in court in the various judicial districts, the writer is afforded perhaps as good an opportunity as any one for observing the problems, the difficulties and the dangers that constantly confront and assail the members of the medical profession

From its very nature and because of the fact that the laity at large is neither interested in nor educated upon questions of science there always has been, there is and doubtless there will continue to be a misunderstanding of the medical profession, its aims and purposes. This misunderstanding is reflected in the courts and in legislative halls, it is a misunderstanding of which charlatans increasingly attempt to take advantage. On the one hand, the medical profession is constantly defending itself in court against attack on the part of individual patients

who are unable or unwilling to understand that no doctor is a guarantor of his work and that despite all efforts, because of the very nature of the human system, bad results now and then are bound to occur. On the other hand, the medical profession must ever be vigilant and on the alert lest state legislatures and the national Congress tie its hands and curtail the means which through scientific study and experience it has concluded are the most proper for its combat against disease and death

It, therefore, behooves the medical profession to stand together against the forces of ignorance and charlatism for the protection of the art which it employs to the best of its ability for the benefit of mankind. Everything possible toward the achieving of a better understanding and a greater concord and unanimity among the ranks of the profession should be sought for and attempted. To its assailants from without the medical profession, if it is to preserve its liberty of decision, must present a vigorous and a united front. No friend of the profession would suggest that individual doctors or groups of doctors are not entitled to their opinions or should be precluded from espousing programs in which they believe, on the other hand, where doctors fail to agree, they must not be surprised when these disagreements are used against them by those who either do not understand or do not sympathize with their aims

No finer statement, no clearer exposition of the need for concord in the medical profession was ever uttered than that found in the first article of the Constitution of the Medical Society of the State of New York, which reads

"The purposes of the Society shall be to federate and bring into one compact organization the medical profession of the State of New York, to extend medical knowledge and advance medical science, to elevate the standard of medical education, to secure the enactment and enforcement of just medical laws, to promote friendly intercourse among physicians, to guard and foster the material interests of its members, and to protect them against imposition, and to enlighten and direct public opinion in regard to the great problems of medicine"

## FOREIGN BODY IN THE EYE—SUBSEQUENT BLINDNESS—ENEUCLEATION

In this action the plaintiff claimed that on the 2nd of August, while engaged in his work as a mechanic and hammering upon the mudguard of an automobile, he was struck in the left eye by a substance which flew from the hammer he was using or from the mudguard he was repairing, that he did not know the nature of the substance but had subsequently been informed that the same was metal, that after sustaining the injury he employed the defendant physician to render him the necessary care and attention in the treatment of his injury, but that the defendant was careless and negligent in his undertaking and failed to use the proper care and skill, so that the plaintiff's injury became more painful, rendering it necessary for him to employ the services of other physicians, that further, by reason of the defendant's alleged negligence, the sense of sight of the injured eye of the plaintiff had become dim and he became gradually blind and that after receiving further treatment, on the 9th of November the plaintiff's injured eye was extracted in order to save him from total blindness, that for these injuries, which he claimed were due to the physician's improper treatment, the plaintiff asked fifty thousand dollars' damages.

The patient was first seen by the defendant on the day he sustained the injury giving a history of having a foreign body in the eye. After examination of the eye the physician co-canceled the eyeball and with the use of a small eye scalpel extracted a foreign body from the patient's eye. The foreign body appeared to the physician to be a piece of dirt. After removing the foreign body an application of boric acid solution was applied to the eye and the patient was given a prescription for a boric acid solution containing camphor and prepared in distilled water and was likewise given a prescription for a ten per cent solution of argyrol for use in his eye. The defendant found a slight condition of ophthalmitis, which was due to the irritation caused by the foreign body. The patient returned two days later and upon examination the condition of the eye seemed to be improving and the patient was instructed to continue the treatment previously prescribed. Some slight inflammation of the conjunctiva was still present. The patient did not return to the physician again until August 10th, at which time the eye was considerably inflamed, but an examination did not reveal any inflammation of the deeper structures.

Because of the persistence of the conjunctivitis the physician felt that the patient might be setting up a condition of iritis or cyclitis and then gave him a prescription for a one per cent atropine, with instructions to put two drops in the eye every four hours. At this time the patient

complained of the eye being very painful. He was also given a one per cent solution of diosmine for the relief of the pain in the eye. August 13th was the next visit made by the patient, at which time, upon examination, it was found that the inflammation had not advanced. The same treatment was continued and the patient advised to return in a few days. He returned on August 17th, at which time it was found that the deeper structures of the eye had become involved.

Under an examination made with an ophthalmoscope, the physician found no interference with the vision except as occasioned by the dilatation of the iris. The conjunctivitis was still present, the iris had lost its brightness and was becoming lusterless, giving evidence of involvement. The lens, aqueous and vitreous of the eye were involved at this time.

The defendant physician concluded that the condition was one for an eye specialist and referred the patient to such a physician. This was the last time that the patient was seen by this defendant.

The patient continued under the care of the eye specialist to whom this defendant had referred him for a period of about six weeks. He then passed into the care of another physician, who saw him on October 25th. To this physician the plaintiff had given a history of the case, stating that he had received treatment from two other physicians. The third physician who saw the patient found upon examination that the eye was very soft and had all the appearances of deterioration and made a diagnosis of irido-cyclitis. He advised the taking of a X-ray and arranged for the patient to enter an eye hospital. The X-ray taken at the hospital revealed an irregular piece of metal embedded in the eye. The patient was advised that the condition of the eye did not permit any attempt to remove the piece of metal, that the eye would have to be removed. On November 9th the eye was enucleated. The post-operative reaction was moderate, with no apparent sloughing of the fatty tissues, the secretion was scanty and apparently healthy. The patient left the hospital on November 15th.

After the enucleation of the eye this action was instituted against the defendant physician and against the second physician, both of them being joined as parties defendant in the same complaint. By a motion the plaintiff was compelled to serve separate amended complaints against each of the defendants upon the theory that they were independent contractors and that they were liable, if at all, for their own independent negligence and that they were not joint tortfeasors. Thereafter the suits continued against both of the defendants individually.

The actions remained upon the calendar for some period of time and the plaintiff made no effort to bring the same on for trial. By reason of his failure to prosecute the actions, a motion

was made on behalf of the defendants to dismiss the actions for lack of prosecution. This motion was granted, thus ending this litigation in favor of the defendant physicians.

### INGUINAL HERNIA—SUBSEQUENT FEMORAL HERNIA

IN this action it was sought to recover damages for the alleged negligent and careless operation upon the plaintiff for a hernia. The complaint charged that prior to January 15th the plaintiff suffered from a hernia and had applied to a hospital for treatment and was referred to the defendant, a surgeon, that the surgeon was employed to attend and treat the plaintiff and to operate for the hernia, that the operation and treatment of the plaintiff by the defendant was negligently and carelessly performed, that the plaintiff was improperly operated upon and improperly allowed to leave the hospital after the post-operative treatment, with the result that the abdominal walls of the plaintiff were again broken down and that he still had a hernia and his testicles were permanently injured, causing him great pain and inconvenience, that it was necessary for him to be again operated upon and that by reason of the injury sustained he was compelled to expend moneys in an endeavor to be cured of his condition and was prevented from attending his usual occupation and had lost the income of his wages.

The plaintiff was seen by the defendant surgeon in the middle of December, at which time he requested the defendant to examine him for a right-sided rupture preparatory to his entering the hospital for an operation for this condition. In making the examination the surgeon held his hand over the patient's right inguinal canal and had him cough. Upon doing so the surgeon felt the protrusion of the bowel in the inguinal canal. This protrusion likewise could be plainly seen. The surgeon could also, on the examination, observe the region of the femoral canal and he is positive that there was no protrusion in this region. He passed his finger through the scrotum and through the external abdominal ring and felt the hernial protrusion above his finger in the inguinal canal. Arrangements were made for his entry into the hospital and the performance of the operation in the middle of the following January.

On January 14th, at the hospital, the patient was prepared for an operation, which was performed by the defendant surgeon. At the time of the operation there was found a small, clear-

cut, decisive and direct inguinal hernial sac, which was operated upon in accordance with the proper and approved methods. The wound healed by primary union. Subsequent to the operation the right testicle became slightly swollen, which was given the necessary and proper treatment. This swelling had practically subsided at the time the patient left the hospital. The patient was out of bed on the thirteenth day after the operation and left the hospital on the following day. After leaving the hospital the patient never returned to the defendant physician. He did, about two weeks after leaving the hospital, return there, at which time he spoke with an interne and stated that he had a recurrence of the hernia and was going to another surgeon to be operated upon.

In the latter part of February of the same year the plaintiff entered another hospital, and upon examination there it was found that he had a femoral hernia. On February 28th an operation was performed for the reduction of the femoral hernia. The plaintiff remained in bed for ten days after this operation and was seen several times by the surgeon who operated. On March 12th the surgeon again examined the patient and found that the incision he had made for the reduction of the femoral hernia had healed and the patient was then released from the hospital. At this time the patient told him that he had been previously operated upon at another hospital for a hernia. This surgeon saw a scar at a point where an inguinal hernia might have been, but the same had healed over very nicely and there was no sign of a recurrence of the inguinal hernia. The two ruptures which the plaintiff had were about one and one-half inches apart and one did not run into the other. They were separate ruptures, one being over the inguinal canal and the other over the femoral canal. A week after the patient had left the hospital he returned to the second surgeon and upon an examination the wounds were found to be entirely healed.

This action remained upon the calendar for some period of time and the plaintiff failing to prosecute the same a motion was successfully made to dismiss the complaint for lack of prosecution upon the plaintiff's part.

# NEWS NOTES

## THE SECOND DISTRICT BRANCH

The year's series of meetings of district branches was completed on Friday evening, January 7, when the Second District Branch convened in the auditorium of the Kings County Medical Society in Brooklyn. The president, Dr Joseph S Thomas, presided, and sixty members were present.

The Second District Branch is unique in that its area comprises an island whose waters make a sharp separation of its four counties from the rest of the State. Its four county societies consist of Kings County, whose medical society combines the functions of a county society and an academy of medicine, and a large library, that of Queens County, whose physicians have to contend with the mushroom growth of a great borough, that of Nassau County which is a suburban section, and that of Suffolk which is still rural. The leaders of the Kings County Society have always been generous in their recognition of the physicians of the other counties, and in assisting them in their activities, especially in post-graduate work. The unity among the county societies is further promoted by the publication of a monthly journal—the *Long Island Medical Journal*—now in its twenty-first year.

Dr George M. Fisher, President of the Medical Society of the State of New York, in his official address, spoke of the vital problems now before the State Society, and of the responsibility of every county society to help in their solution. He commended the annual message of Governor Alfred E. Smith, especially those paragraphs relating to the establishment of county health officers and the practice of medicine act (see page 89). He warned the County Legislative Committees to continue their activities, and to keep in touch with their legislators, and so be prepared to combat any bills that may be introduced. The State Medical Society has no major bills to promote this year.

Dr Fisher also dwelt on the functions of the District Branches, and urged the members to consider topics and activities of a civic nature. The meetings of the State Society and the post graduate courses of the county societies are supplying the scientific instruction to the members. The function of the District Branches is to encourage the county societies in their own peculiar activities as distinguished from the work of individual members.

Dr D. S. Dougherty, Secretary of the State Society, spoke on the individual responsibility of the members of county societies.

Representatives of the four county medical societies of the Second District Branch told of the work of their societies. Dr W. H. Ross described the activities of the Suffolk County Medical Society, of which the outstanding feature was the assumption of leadership in all the activities in which lay organizations are interested.

His address is published in full on page 66.

Dr Louis I. Neff, lay secretary of the Nassau County Medical Society, described the work of the society which he represents. The Nassau County Society has a membership of about 140, and employs Mr Neff as its Secretary and Treasurer. The result is that records are well kept, dues are collected, members are notified of activities, and correspondence is kept up to date. The annual local dues of the Society are ten dollars, and Kings County is the only one whose dues are larger. The size of the dues does not keep doctors from joining, but on the other hand the activities which the dues make possible encourage physicians to seek admission.

The Society meets on the fourth Tuesday evening of each month, and begins each meeting with a dinner, followed by the business and scientific session. The average attendance is around thirty.

The plans for the coming year call for two speakers at each scientific session, one to be a member of the local society and one to be invited from outside.

The outstanding activity of the Nassau County Medical Society is its weekly post-graduate clinical lecture given every Thursday afternoon at 3:30 o'clock in the Nassau Hospital, Mineola. These lectures will be continued during the winter and spring. They are attended by an average of thirty doctors.

Mr Neff also described the A. M. A. insignia used by members on their automobiles. He said that the police all over the county respect the insignia since they know that each one is registered with the County Medical Society, and the Society guarantees the honesty and reliability of the driver.

Mr Neff closed with a description of the studies now being made by the Society regarding the need for more hospitals and dispensaries.

Dr Edward A. Fleming, of Richmond Hill, described the activities of the Queens County Medical Society. His address is published in full on page 68.

Dr Alec N. Thomson, Secretary of the Public Health Committee of the Kings County Medi-

cal Society and Editor of the *Long Island Medical Journal*, exhibited stereopticon transparencies prepared for lay audiences, showing the activities of the Kings County Medical Society. The Kings County Society has always worked with the lay health organizations of Brooklyn, and directed them in their medical activities, and in return the lay organizations and political workers have welcomed the advice of the doctors.

Three brief papers by Brooklyn members were presented during the scientific session.

Dr. John E. Jennings gave a paper on epiglottitis, and illustrated his talk with lantern slides of the omentum in various stages of thickening and contraction.

Dr. Walter D. Ludlum described his present practice in dealing with diphtheria and scarlet fever from both the curative and the preventive points of view.

Dr. Tasker Howard read a paper on "Side-lights on the Art of Physical Diagnosis in which

he reviewed briefly some points which he had found useful in making physical examinations. He said, for example, that a mild jaundice might not be noticed if the skin were examined by yellow artificial light, and he described methods of judging the size of the heart by means of the location and extent of the apex beat, and of examining the liver by placing the hand above the liver with the fingers pointing down instead of up. The points which he brought out were simple and almost self-evident, but the doctor who has them conscientiously in mind can make a superior physical examination.

The following officers were elected for two years beginning at the close of the Annual Meeting of the State Medical Society: President, Dr. Guy H. Turrell, Smithtown Branch, First Vice-President, Dr. Charles A. Gordon, Brooklyn, Second Vice-President, Dr. Louis G. Van Kleeck, Manhasset, Secretary-Treasurer, Dr. F. H. Richardson, Brooklyn.

---

## COMMITTEE ON PUBLIC RELATIONS

The friendly relations between the medical profession of New York State and the lay organizations engaged in public health work will be greatly promoted by the action of the Council of the Medical Society of the State of New York in appointing a committee to confer with a similar committee of the State Charities Aid Association. The action of the Council was in response to the following communication from Mr. Homer Folks:

November 26, 1926

Dr. George M. Fisher, President

"Dear Dr. Fisher:

"I am instructed by the Executive Committee of the State Committee on Tuberculosis and Public Health to lay before you the question as to whether it might not be useful if the State Medical Society would designate a committee to sit with a similar committee from the State Committee on Tuberculosis and Public Health for the purpose of considering problems arising on the common ground between medical practice and public health, with a view to bringing about better understanding, and so far as practicable, harmonious action in the common interest of all concerned. I am instructed to say further that this Executive Committee is of the opinion that such a step would be desirable, and has authorized its chairman to appoint representatives to participate in such conferences should the State Medical Society consider it advisable to follow a similar course.

"Among the considerations which have led to the above suggestion are these:

"1. New questions are coming forward from time to time in various localities in the state in which both the official and unofficial health agencies and also the medical profession are deeply concerned. From time to time, presumed differences of opinion arise which result in criticisms, misunderstandings, and waste of effort.

"2. It has often happened that when an informal group of physicians and health workers have undertaken to consider seriously and in detail a matter which has been the subject of criticism, it has been found that such criticism has been due to misunderstanding on one, or on both sides, of the plans, purposes and objectives of the other.

"3. It has also been found in such informal conferences that difficulties and criticisms have arisen because neither party concerned had given really close, serious, and analytical consideration to the actual questions involved. For many of these questions there are no former precedents and they require, therefore, detailed consideration and hard thinking. It has been easier for both sides to slip into the position of criticising the other, than of offering seriously considered constructive proposals.

"These are some of the reasons which have led us to feel that conferences of the nature above indicated might be very fruitful at this time in the development of medical

practice and of public health activities in this state

"May I add, in passing, that it has been of very great value, indeed, to the State Committee on Tuberculosis and Public Health to have the former and the present President of the State Medical Society in its active membership"

I am, sincerely yours,

HOMER FOLKS,  
*Secretary*

The council took favorable action on this invitation at its meeting on December 9, and voted to appoint a special committee of five, to be

known as the Committee on Public Relations, "To meet representatives of the State Committee on Tuberculosis and Public Health for the purpose of discussing their several fields of activity in public health, with the object of determining how our two organizations can best supplement each other so as to secure the highest efficiency with the least overlapping of activities in our mutual effort to serve the public"

The committee appointed consists of Dr G W Cottis, Jamestown, Chairman, Drs Wilbur T Fish, Ithaca, T P Farmer, Syracuse, W W Britt, Tonawanda, Terry M Townsend, 498 West End Avenue, New York City, and the Executive Officer of the State Society, Jos S Lawrence, Albany

## CATTARAUGUS COUNTY

At a meeting of the Cattaraugus County Medical Society held on December 16, 1926, the Committee on Public Health made the following report, which was adopted

To the members of the Medical Society of the County of Cattaraugus

Your Committee on Public Health, at the last regular meeting of the Medical Society of the County of Cattaraugus, was requested to consider the matter of the relation of the Society to the public health work carried on in Cattaraugus County by the County Board of Health and the County School Hygiene District

We herewith submit our report.

At the annual meeting of the National Tuberculosis Association in 1922 an announcement was made that the Milbank Memorial Fund would undertake a program of three health demonstrations in New York State. One of these was to be in a rural county, one in a medium-sized city, and one in a district metropolitan in character

The Board of Trustees of the Milbank Memorial Fund, on the advice of a Technical Board which it had appointed, designated the State Committee on Tuberculosis of the State Charities Aid Association as the chief operating agency for the rural and medium-sized city demonstrations

The Board of Trustees of the Milbank Memorial Fund consists of a number of distinguished laymen and a physician. The secretary of this Board of Trustees is Mr John A Kingsbury

The Technical Board consists of the following members: Bailey B Burrett, John A Kingsbury, Homer Folks, Livingston Farrand, M D, James A Miller, M D, Mathias Nicoll, M D, Linsly R. Williams, M D, William H Welch, M D

In addition to this there is an Advisory Council of the Milbank Memorial Fund consisting of a large number of prominent lay and medical

leaders in public health. The secretary of this Advisory Council is also Mr John A Kingsbury

The State Committee on Tuberculosis and Public Health of the State Charities Aid Association has a large membership of prominent people, mostly laymen, and contains in its membership two members from Cattaraugus County, Miss Lilla Wheeler of Portville, and Dr C A Greenleaf of Olean

This committee is governed by an executive committee of which Mr Homer Folks is secretary. The executive secretary of the staff of this committee is Mr George J Nelbach, and the assistant in Preventive Medicine is Dr A C Burnham

Late in 1922 the Medical Society of the County of Cattaraugus, the various chambers of commerce, various service clubs, and other organizations, including the Cattaraugus County Tuberculosis Association, which is the County Branch of the State Charities Aid Association, all passed resolutions inviting the State Committee and the Milbank Memorial Fund to consider Cattaraugus County for the site of their rural demonstration

Twelve counties in the state were considered, and in November, 1922, Cattaraugus County was chosen and approved by the Technical Board and the directors of the Milbank Memorial Fund

In January, 1923, the general health district or County Board of Health was established by the Board of Supervisors. It is recalled that members of this Society appeared at the meeting of the Board of Supervisors at which this measure was considered, prepared to speak in favor of its adoption

Salamanca and Olean, by vote of their municipal councils, both joined the Health District. This action was necessary on their part under the law before they could be included

In April, 1924, a conference on the program of the County Board of Health and other official

and unofficial bodies in the county receiving aid from the Milbank Memorial Fund was held in Albany

This conference was attended by the State Commissioners of Health and Education, the division chiefs of the State Department of Health, the head of the State School Medical Service, and some of the bureau chiefs of the Cattaraugus County Board of Health, and the president of the Medical Society of the County of Cattaraugus, who was at that time Dr S H Bennett, of Little Valley

The phases of the work program included tuberculosis, communicable disease, school hygiene, sanitation, infancy and child hygiene, venereal disease control, mental hygiene, and health conservation and life extension

Dr Bennett, as president of this Society, is stated by officials of the Milbank Memorial Fund, to have been present at the conference and to have given approval to the program as outlined and adopted. We can find no record in the minutes of this Society of a report on this conference, nor any record of a resolution empowering anyone to approve or act officially for the Society

The object of the demonstration, as the activities of the County Board of Health, County School Hygiene District, and the unofficial County Tuberculosis and Public Health Association are collectively termed, is to set up in Cattaraugus County public health practice similar to those well established in cities and some counties in the United States, further, to assist in the formative stage of this program with financial aid, and expert advice, is the function of the Milbank Memorial Fund, and the other agencies listed above.

When the organization is complete, functioning properly and receiving enthusiastic support from local sources, it is the ultimate aim of the Milbank Memorial Fund to withdraw from the county. However, advisory assistance and, if necessary, financial aid to perfect an ideal county unit is promised, we understand

The County Board of Health consists of seven members. These are appointed by the Board of Supervisors. Two of the members must be and are physicians, and are appointed by the Board of Supervisors following the recommendation of your Society

The members are as follows: Miss Lilla Wheeler, Mr John Walrath (president), W A Dusenbury, William Bushnell, James Watson, Dr M E Fisher, Dr M L Hillsman

The county health officer is appointed by the County Board of Health, with the advice and assistance of the officials of the Technical Board of the Milbank Memorial Fund, and the operating agent, the State Committee on Tuberculosis and Public Health of the State Charities Aid Association

The present county health officer is Dr Stephen A Douglass, a graduate of Starling Medical College. Dr Douglass was formerly director of the Bureau of Tuberculosis of the Cattaraugus County Board of Health, and before that the chief of the tuberculosis services of all the National Homes for Disabled Soldiers. He has always been active in public health work, and during the World War obtained large experience in organization as an officer of the American Red Cross overseas. Dr Douglass succeeded Dr L D Bristol in February, 1925, and since that time has been responsible for the organization of the present program of health activities in the county

#### • CONSIDERATION OF PRESENT ACTIVITIES

*Bureau of Public Health Nursing* There are at present 18 nurses employed by the county. Each has an allotted district and works under the supervision of a general director, who is called The Director of the Bureau of Public Health Nursing. This director is a nurse, and of large experience in public health. In addition there are 4 special supervisors whose duties have to do with special branches of public health work, namely school nursing, tuberculosis nursing, social hygiene nursing, and maternity, infancy and child hygiene nursing. The nurses in their districts have as their duties routine public health work as follows: school inspections, child hygiene work, follow-up work in the correction of defects, tuberculosis follow-up work, the development of home care of the sick (especially the tuberculous, with a minimum of bed-side nursing)

In general they cooperate with and assist all other branches and further public health by co-operation with all local agencies and voluntary nursing organizations. All phases of their work are purely of a nursing, that is, public health nursing, character. They are instructed to carefully refrain from interfering with medical practice, to assist local physicians as far as possible, and to discretely disseminate public health information

*Bureau of Laboratories and Communicable Diseases* The personnel of the Laboratory and Bureau of Communicable Diseases combined consists of a director, who is a physician, two technicians for the laboratory, and part of the services of a well trained statistician and clerk for communicable diseases. One of the technicians in the laboratory is qualified to do all the recognized laboratory tests, the other is not. The laboratory is equipped to do and is doing the usual chemical and bacteriological tests. All specimens are sent in by the profession, with the exception of a few medico-legal specimens. In but few instances are specimens accepted from nurses and then only under the direction of a physician, or with his knowledge

The rules regarding this phase are specific and

rigidly enforced Laboratory supplies are furnished gratis to any physician promptly Reports are given only to physicians

The Director is available and is used for laboratory consultations

Communicable diseases are reportable by the local health officer to the county health officer Investigations of cases, the establishment of quarantine and its enforcement, the employment of other recognized measures for the control of infectious and contagious disease is the joint duty of the local health officer and this Bureau Under the latter comes smallpox vaccination, and diphtheria toxin-antitoxin These activities are and will be done by local health officers and private physicians cooperating with the County Board of Health

*Veneral Disease Control* Cases are treated in free dispensaries There are two dispensaries, one operated by the City of Olean Department of Health, and one in Salamanca, operated by the city and county boards of health jointly Only cases referred by their physicians or cases under compulsory treatment are accepted

In connection with the consideration of communicable disease activities physicians are urged to promptly report all communicable diseases and aid as far as possible in the compilation of statistics

*School Medical Service* This is not really a part of the County Board of Health, but is a department of its own The Director is a physician, and is not under the authority of the county health officer However, as the county health officer is also Director of the Demonstration of the Milbank Memorial Fund, and as the County School Medical Service is a part of the Demonstration and receives funds therefrom, the Director of the Demonstration is indirectly interested in this service

This service is county-wide in scope Routine inspections are done by the nurses of the County Board of Health but these are in no sense a physical examination They consist merely in a preliminary survey of the children in order that beginning defects or contagious disease may be discovered as early as possible Frequent inspections are the rule, therefore All reports are sent to the family physician

Routine physical examination will always be done by the local school physician appointed by the local school board Under the law, we understand, these are to be done yearly, but it is felt that a three year examination rule is desirable and the profession is asked to advocate such a change in the law Physical defects and other conditions are reported to the family physician Remedial measures are in the hands of the family physician The school medical service cooperates with the physician at all times to bring about the desired effect in correction of physical defects and malnutrition among school children

*Bureau of Maternity, Infancy, and Child Hygiene* It is hoped by the establishment of this bureau there will occur a reduction in the death and morbidity rates of expectant mothers and of babies This it is planned to do by (a) educational measures (b) remedial measures (c) proper instruction to pregnant women and mothers in prenatal and postnatal care, and the urging of routine examinations and the employment of laboratory facilities In the educational measures systematic group and individual instruction, dissemination of pamphlets and literature, and nursing visits are employed In the medical line prenatal clinics, postnatal clinics, child conferences, and well baby clinics are or will be established It is contemplated to hold prenatal clinics by the director of this bureau with local physicians in charge and the director in an advisory capacity The director of the bureau plans for and urges a rotary service of the local physicians in this work All reports will be sent to the family physician and his consent and advice solicited in every case At the child conferences and well baby clinics local physicians will be used and compensated Advice on the care of the child and such other information as will not conflict with the private physician will be given Minor suggestions on dietary and medicinal care are of necessity brought up at these clinics However, the director is extremely desirous of arranging this phase of the work so that it will be acceptable to the profession

*Bureau of Tuberculosis* The efforts of this bureau are intensive case finding by holding "chest" clinics in the various centres throughout the county These clinics are held by the director of the bureau, assisted by the resident physician at the county sanatorium Private physicians interested in this work are asked to actively assist in examinations

The clinics are open to the public without discrimination and will be so in the future, or at least until the case-finding campaign is completed However, it is significant that fully 70% of the examinations were on patients referred by the private physician All examination reports are mailed promptly to the family physician Individual examinations outside of clinics at the request of the attending physician are done by the director In the future the director is desirous to assist in outside consultations at all times

No treatment nor information bearing on treatment is given patients nor will there be in the future Advice will only be given when authorized by the physician

A great deal of control work is necessary by this bureau and is undertaken by this bureau working in conjunction with the physicians and public health nurses Home sanatorium treatment is an educational measure and it is the duty of the public health nurse with the aid of the attending physician to see that these measures are enforced

**Bureau of Public Health Education** This department from the physicians' viewpoint is a very important one. It is in charge of a full-time director whose duties are the education and informing of the public in health matters and health conservation by lectures, printed material, and other means. He calls upon the various specialized speakers of the State Department of Health as well as other well-known health authorities. Private physicians will recognize the value of this bureau.

**Bureau of Sanitation** The proper sanitary procedures are or will be developed in this county by this bureau. At present there is one inspector whose services are available and used by the local health officers of the county.

**Bureau of Statistics** This bureau is charged with the compilation of figures which will form or are forming a more valuable basis for estimating the results of this health work. Records are kept carefully. The prompt reporting of communicable diseases, and births, and the other reports by physicians will facilitate this work.

By adherence in principle to the foregoing the County Board of Health hopes to accomplish the following:

(1), A reduction in the general death rate, (2), lower the incidence of communicable disease and reduce physical defects and malnutrition among school children, (3), lower the death rate in babies and expectant mothers, (4), reduce the incidence of tuberculosis and venereal disease, (5), improve economic conditions since sickness contributes to poverty and crime; (6), increase universal periodic health examinations, (7), a

general improvement in the general health of the county.

In summary the public health committee of the County Medical Society have carefully studied the contemplated activities of the County Board of Health and urge the adoption of their program. The County Health Unit is basically sound and desirable, and should be supported by the physicians of the county.

**Recommendations** Your Committee on Public Health recommends that the Society go on record as favoring the present day public health movement, as favoring the county health unit as the most practical unit in public health administration, as expressing its appreciation to the Milbank Memorial Fund for enabling Cattaraugus County to test the value of the county health unit idea, as expressing its confidence in the members of the County Board of Health and as favoring cooperation with the County Board of Health of the organized medical profession of the county.

Your committee further recommends that the Society go on record, in view of the fact that the Society and its members individually are interested in public health and the prevention of disease, and in view of the fact that the cooperation of the Society and its members as individuals has been solicited in the task, as approving of the criticism in a constructive way of the actions, activities, programs and plans of the County Board of Health and the other official and unofficial public health bodies in Cattaraugus County.

L J ATKINS, *Chairman*.  
A L RUNALS,  
P H BOURNE

## THE CHIROPRACTIC HEARING

The joint committee of the Senate and Assembly appointed last spring to investigate the practice of chiropractic and to suggest what legislation is needed for its regulation, held sessions on December 22 and 23, in the Alderman's room of the City Hall, New York City. The members of the Committee are Senator John L. Karle of Queens County, Chairman, Senator Henry G. Schackno of New York County, and Assemblyman Howard N. Allen of Dutchess County, John F. Reidy of Bronx County, and Frank M. Smith of Otsego County.

The Committee was given an appropriation of \$5,000 for its expenses, and was instructed to report by February first, 1927. It has employed Mr. Alexander Otis as its counsel, and the announcement was made that he was to be consulted by all who wished to be heard, and that there would be no cross examinations. The two hearings progressed in a dignified manner. The procedure was that Mr. Otis first examined the witness in order to elicit his points in a brief

concise form, and then the witness was questioned by members of the committee, especially Mr. Schackno. There were no hecklings or insinuations, but the questions and answers were made calmly and fairly.

Both hearings were occupied by the chiropractors, who were given every opportunity to state their case in a scientific, logical manner. Their witnesses answered questions directly and with little or no show of feeling. They were evidently accustomed to public appearances, and realized that the force of their arguments was promoted by courtesy and self-confidence, especially confidence.

The hearings were attended by a few representative physicians, and by about fifty chiropractors. The audience was generally orderly and undemonstrative and only once was applause heard, and that was by the chiropractors over an inconsequential sally. The atmosphere of the hearing was one of truth seeking and of oppor-

tunity for the proponents of chiropractic to present their case freely

The first witness was James N Firth, who had been a public school teacher before he took up chiropractic. He teaches diagnosis and symptomatology in the Lincoln School of Chiropractic, at 518 North Delaware Street, Indianapolis, Indiana. He is a licensed chiropractor in Indiana, Illinois and Iowa. He had completed a one year course in the Palmer School in Davenport, Iowa, in 1909, and a three year course in 1916, and had then established the Lincoln School of Chiropractic in Indianapolis.

Mr Otis asked Mr Firth to state what chiropractic is. The witness said in substance: Chiropractic is a system of drugless practice, recognizing that the human body is composed of living flesh, which works when actuated by a living force originating in the brain and passing out by means of nerves. This force animates all the organs and controls heat, nutrition, secretion, excretion, and all other vital actions. It is impeded in its passage by displaced bones. The witness continued his discourse at some length until Chairman Karle suggested that he get to the point immediately and tell the principles by which the chiropractor applies his treatment. Mr Firth took an articulated spinal column in his hand and talked about the details of the intervertebral foramina through which the nerves pass as they leave the spinal cord. The foramina, he explained, are oval, and the nerves are also oval, but their long axes lie in the short axes of the foramina and are therefore readily compressed. The nerve is hung in the upper half of the foramen as is shown by a cut in a standard textbook on neurology which the witness exhibited. The witness did not point out the foramina on the spinal column which he held, nor use it in showing how he manipulated the vertebrae in his treatments.

Mr Firth was reminded by Chairman Karle that the committee wished to know what he did to the vertebrae which were out of place. He replied with a lengthy dissertation on the intervertebral discs, saying that they were composed of a net work of fibres in which a jellylike substance was enmeshed. When the spine is tilted, the jelly is squeezed out of one side, and the permanency of the injury depended on how compressed and dry the disc became. If only a few cells, microscopic in size, were dry, one or two treatments might restore the disc, but if the disc is dry and hard, the chiropractor may not be able to put the pulp back quickly.

The witness also described at some length how the act of bending the spine sideways raises the superior articular process of a vertebra and produces a subluxation which reduces the size of the foramen. By a subluxation the witness said he meant a partial dislocation in distinction from a luxation, or complete dislocation.

Treatment is by means of what is called the

thrust, which is applied according to the indications found after inspection and palpation of the spine, in order to find the relations of the parts which can be felt, especially the spinal and transverse processes. A record is made of the direction of the displacement and the amount.

When asked if a diagnosis of impingement on the nerves was all that a chiropractor needed, Mr Firth replied "No, not entirely. Progress in treatment depends on the extent of the damage. I can't tell how extensive is the damage. I should have some knowledge of structural changes so as to know if the damage is irreparable."

In reply to the question "How would a chiropractor discover an impingement of a spinal nerve," the witness answered "By the symptoms, by tenderness of impinged spot and the palpable position of the vertebrae. The diagnosis is by the spine itself."

The witness told in some detail how he would replace a vertebra. If it was tilted forward, for example, he would press upon its spinous process to tilt it back. The movement might be only one five-hundredth of an inch at a treatment, but the vertebra could finally be replaced.

Mr Firth denied that he had said that chiropractic would cure all diseases, but he admitted that that was the implication, although some conditions could not be reached. He used a stethoscope, but sent urines to a laboratory for examination.

Members of the investigating committee then asked Mr Firth questions regarding chiropractic schools. He said that when he entered Palmer School, there were no educational requirements. Palmer gave instruction in anatomy, histology, physiology, orthopedy, symptomatology, adjusting and the theory of chiropractic.

The Lincoln School of Chiropractic was organized in September, 1916. It requires certificates of good moral character and a reasonably good intelligence which is determined by the letters and conversation of the applicant. He said that some applicants are denied admission. His school has no hospital. It has fifteen students. It is not licensed by any governing authority such as the Regents of the State of New York. It is a corporation with \$60,000 capital. It charges \$600 for the three year course. It has not yet declared a dividend, but will distribute its profits to the stockholders when it earns the money. When he was asked if he knew of other professional schools that were run solely on their tuition fees, he named the Ferris Institute, which gives instruction in shorthand, kindergarten, college preparation and other subjects. He said that all chiropractic schools were run on fees and none had an endowment. As for the schools being conducted for profit, he said the teachers had at least to make a living out of them.

Mr Firth was over an hour in giving his tes-

timony His evident intention was to tell what chiropractic is, and in this he was given every opportunity

The next witness was Dr Frederick A Fischer, who has an office in the Otis Building, Philadelphia, Pa He had spent two years in a high school and had graduated from a pharmacy school and then graduated from the Hahneman Medical School, Philadelphia, in 1895, with the degree of Doctor of Medicine, but he did not serve an internship and has not been connected with a hospital except for five years in an outpatient department He spent two years in a high school and in 1910 he took a six months' course in the Marschand School of Chiropractic, Philadelphia His course was short because he needed only the purely chiropractic part He is a member of the Medical Society of the State of Pennsylvania, and of the County of Philadelphia, of the Institute of Homeopathy and of the Germantown Medical Society He practices both medicine and chiropractic and considers them distinct from each other, although he considered a knowledge of medicine necessary in order to practice chiropractic He has no sign of chiropractic on his door, for his patients know that he gives that form of treatment.

Dr. Fischer told why he took up chiropractic. He had met a doctor friend whose wife a chiropractor had cured of blindness following retinal hemorrhages Dr Fischer went to the friend who seems to have practiced chiropractic and was cured of headaches and intestinal stasis He then took a course in the Palmer School of Chiropractic and practiced adjustments He tried it on a man, aged 24, who had typhoid fever, but was unsuccessful at first, for he did not know that the sicker the patient was the more rigid was his spine. At the end of the fourth week the patient had a hemorrhage and Dr Fischer realized that he would have to adjust the vertebra in order to save the patient's life, and so he took the patient out of bed and with much force he put the second lumbar vertebra in place and from that moment the patient got well

Dr Fischer then described the cure of a boy with rheumatism, a girl with paralysis following a fall down stairs, a boy of 13 at Nanticoke Pa, who had never walked, a girl who was delirious with pleurisy and was made well by a single treatment. He also said that his mother and sister had died of tuberculosis and his aunt had the disease, but no more cases had developed in the family since he had taken up chiropractic

After Dr Fischer had ended his direct testimony, he answered the following questions

Q Do you regard medicine and chiropractic as separate and distinct sciences?

A Yes

Q Is it necessary for a chiropractor to have all the education of a doctor of medicine?

A Not all

Q To what extent might his education be limited and he still be a good chiropractor?

A He should be able to diagnose by physical diagnosis, not by bacteriology or by chemistry

Q Assuming that a chiropractor is not a physician, could he diagnose a case by the spine and the history?

A I can put my hand on a spine and can tell what organs are sick

Q Could a chiropractor, who is not a doctor, make a diagnosis?

A He would need to take the temperature, to examine the chest, and abdomen He should know what organs are diseased

Q You took six months to learn chiropractic, was that enough?

A No An ordinary man would need three courses of six months each

A Would that be enough to make him useful to the community?

A Yes

Q Do you believe in premedical courses?

A They do not improve the man or make him a better doctor

Q Do you know of any medical college run as a business corporation?

A No

Q Is the public served by a chiropractic school?

A Yes

Q Is it good policy for an institution for public good to be run privately?

A Not as a rule.

Q Do you recognize a deficiency in the subjects taught to chiropractors?

A Yes, in the past The schools are adding physical diagnosis and bacteriology

Q Do you know of any chiropractic school that has an interne?

A No

Q Do the students go from the chiropractic schools directly into practice?

A Yes

Q Do you as a practitioner of medicine think this is good?

A No, but they get results

The second session of the chiropractic hearing was held on the morning of Thursday December 23, in the City Hall The first witness was Judge Herbert Vander Zee, who has been the counsel for the State Association of Chiropractors for five years He submitted a digest of the laws of the several states relating to chiropractic From a study of these laws the Judge concluded that it was the policy of the states to recognize and license chiropractors The states of Oklahoma and California had refused to recognize the chiropractors until a referendum in each showed an overwhelming sentiment in their favor

The Judge then gave a brief history of the

tunity for the proponents of chiropractic to present their case freely

The first witness was James N Firth, who had been a public school teacher before he took up chiropractic. He teaches diagnosis and symptomatology in the Lincoln School of Chiropractic, at 518 North Delaware Street, Indianapolis, Indiana. He is a licensed chiropractor in Indiana, Illinois and Iowa. He had completed a one year course in the Palmer School in Davenport, Iowa, in 1909, and a three year course in 1916, and had then established the Lincoln School of Chiropractic in Indianapolis.

Mr Otis asked Mr Firth to state what chiropractic is. The witness said in substance: Chiropractic is a system of drugless practice, recognizing that the human body is composed of living flesh, which works when actuated by a living force originating in the brain and passing out by means of nerves. This force animates all the organs and controls heat, nutrition, secretion, excretion, and all other vital actions. It is impeded in its passage by displaced bones. The witness continued his discourse at some length until Chairman Karle suggested that he get to the point immediately and tell the principles by which the chiropractor applies his treatment. Mr Firth took an articulated spinal column in his hand and talked about the details of the intervertebral foramina through which the nerves pass as they leave the spinal cord. The foramina, he explained, are oval, and the nerves are also oval, but their long axes lie in the short axes of the foramina and are therefore readily compressed. The nerve is hung in the upper half of the foramen as is shown by a cut in a standard textbook on neurology which the witness exhibited. The witness did not point out the foramina on the spinal column which he held, nor use it in showing how he manipulated the vertebrae in his treatments.

Mr Firth was reminded by Chairman Karle that the committee wished to know what he did to the vertebrae which were out of place. He replied with a lengthy dissertation on the intervertebral discs, saying that they were composed of a net work of fibres in which a jellylike substance was enmeshed. When the spine is tilted, the jelly is squeezed out of one side, and the permanency of the injury depended on how compressed and dry the disc became. If only a few cells, microscopic in size, were dry, one or two treatments might restore the disc, but if the disc is dry and hard, the chiropractor may not be able to put the pulp back quickly.

The witness also described at some length how the act of bending the spine sidewise raises the superior articular process of a vertebra and produces a subluxation which reduces the size of the foramen. By a subluxation the witness said he meant a partial dislocation in distinction from a luxation, or complete dislocation.

Treatment is by means of what is called the

thrust, which is applied according to the indications found after inspection and palpation of the spine, in order to find the relations of the parts which can be felt, especially the spinal and transverse processes. A record is made of the direction of the displacement and the amount.

When asked if a diagnosis of impingement on the nerves was all that a chiropractor needed, Mr Firth replied: "No, not entirely. Progress in treatment depends on the extent of the damage. I can't tell how extensive is the damage. I should have some knowledge of structural changes so as to know if the damage is irreparable."

In reply to the question "How would a chiropractor discover an impingement of a spinal nerve," the witness answered: "By the symptoms, by tenderness of impinged spot and the palpable position of the vertebrae. The diagnosis is by the spine itself."

The witness told in some detail how he would replace a vertebra. If it was tilted forward, for example, he would press upon its spinous process to tilt it back. The movement might be only one five-hundredth of an inch at a treatment, but the vertebra could finally be replaced.

Mr Firth denied that he had said that chiropractic would cure all diseases, but he admitted that that was the implication, although some conditions could not be reached. He used a stethoscope, but sent urines to a laboratory for examination.

Members of the investigating committee then asked Mr Firth questions regarding chiropractic schools. He said that when he entered Palmer School, there were no educational requirements. Palmer gave instruction in anatomy, histology, physiology, orthopedy, symptomatology, adjusting and the theory of chiropractic.

The Lincoln School of Chiropractic was organized in September, 1916. It requires certificates of good moral character and a reasonably good intelligence which is determined by the letters and conversation of the applicant. He said that some applicants are denied admission. His school has no hospital. It has fifteen students. It is not licensed by any governing authority such as the Regents of the State of New York. It is a corporation with \$60,000 capital. It charges \$600 for the three year course. It has not yet declared a dividend, but will distribute its profits to the stockholders when it earns the money. When he was asked if he knew of other professional schools that were run solely on their tuition fees, he named the Ferris Institute, which gives instruction in shorthand, kindergarten, college preparation and other subjects. He said that all chiropractic schools were run on fees and none had an endowment. As for the schools being conducted for profit, he said the teachers had at least to make a living out of them.

Mr Firth was over an hour in giving his tes-

## THE GOVERNOR'S ANNUAL MESSAGE

Governor Alfred E. Smith has always shown himself favorable to measures for the promotion of public health, and has been a foremost promoter of those aspects of civic medicine whose practice requires the cooperation of the State. His annual message to the Legislature contains whole paragraphs which set forth the policies of the administration on several public health topics which are under consideration.

Believing that the Governor's views are of interest to every physician and that doctors generally approve his opinions and conclusions, we are printing those parts of the message which pertain to health. The extracts are taken from the text as printed in the *New York Times* of Thursday, January 6, 1927.

### MOTOR VEHICLE OPERATION

Safety on the highways is a matter of deep concern to the State. Remembering that it took several years to convince the Legislature of the necessity for a State-wide control of motor vehicle operation, it is even more gratifying to record the success of the Bureau of Motor Vehicles in cutting down the number of deaths caused by motor vehicle operation. Notwithstanding that there are 191,000 more automobiles registered this year than during 1925 and over 200,000 additional licensed drivers, deaths due to motor vehicle operation during the calendar year 1926 are 2,093, as compared with 2,120 during 1925.

The successful cooperation between the public at large and the officials charged with the administration of the motor vehicle law is in no small measure responsible for the decrease. When we consider that nearly 20,000 reckless, careless, incompetent or intoxicated drivers were taken off the highways of the State during the last twelve months and that nearly half the applicants for driver's licenses were rejected, the efficacy of the law is apparent.

### GRADE CROSSINGS

Unquestionably, one of the most important steps taken by the State in recent years for the preservation of human life and property was the amendment to the Constitution placing the State in position to finance the State's share and to help the State's partners in the work of the elimination of dangerous railroad crossings at grade.

There seems to have arisen in the extremely rural districts a pronounced disinclination to proceed with the work of railroad crossing elimination. This is undoubtedly due to the tax burden added to the small localities to pay their one-fourth share of the cost. Until the smaller municipalities are relieved of some part of their share of the cost of elimination, activities will in general be confined to the more wealthy districts of the State.

Your honorable bodies put forward last year and passed for the first time a new amendment to the Constitution which will permit the county to come to the aid of the smaller unit. I would suggest that at the earliest possible moment we have a joint conference between the agencies of the Government charged with the work and representatives of the Legislature. I will be very pleased to attend such a conference in order that we may map out a definite program to treat this grade crossing proposal as something of State-wide interest, which it really is.

Since the dairy industry of the State is so very important and with the growth of population in the cities there is such demand for milk and cream, the State has devoted considerable attention to the protection of the milk supply. One important phase of this has been the protection of the public health against bovine tuberculosis. Since 1924, the Department of Agriculture has adopted a unit for control based on the township, so that there is now a definite standard of measurement of progress. Beginning with a cattle population of 2,000,000 and widespread and deep-seated infection, the difficulties of eradication can easily be appreciated. With a definite goal of complete elimination in 940 townships, it is gratifying to know that the work has been completed in over 470 of such units. In other words, more than half are now in good condition.

I urge upon you that there be no curtailment of this work, but that its encouraging results be carried through to a 100 per cent eradication of this menace to the public health.

### RURAL POPULATION

It is noticeable that the drift from the country to the cities continues. In 1917 there were 890,000 people living on the farms of the State. This number had fallen on Jan. 1, 1925, to 767,500. This is not due in any large measure to unfavorable living conditions in the country but to the disparity of economic opportunity between the farm and the city workshop.

With intelligent State planning and proper distribution of hydroelectric energy some of this urban population may again return to less densely populated communities and benefit the agriculturist by providing markets closer at hand and making transportation less expensive and hazardous.

The State's solicitude for its rural population, as is indicated by the reports not alone of the Department of Agriculture but of the Departments of Public Health, Conservation and other State agencies, is undoubtedly making itself felt in improved conditions and better returns for the farmer.

### PUBLIC HEALTH

Among those diseases and conditions which are unquestionably preventable within our present

proposed chiropractic laws of New York State. A chiropractic bill was passed during the first year of Governor Smith's term of office, but the Governor had vetoed it on the ground that the policy of the state was to maintain the Regents as the single board of examiners in all educational requirements.

The Judge said that the bills for the past five years would require the chiropractors to pass all medical subjects except obstetrics, surgery and materia medica.

Regarding the waiver clauses admitting all present chiropractors to practice, the Judge said "As a general proposition all professional experience in the past has been accepted as a qualification to practice."

The next witness was Dr. Frederick H. Hirschland, a graduate in medicine from a German University but not licensed in New York State. He taught pathology in the Flower Hospital at one time and is now treasurer of the New York School of Chiropractic which was established in 1912 at 124 West 74th Street, New York, and now has 75 students and 4 teachers. The students come from all over the world—Japan, Canada, Australia and France and represent a "League of Nations."

The school has a paid up capital of \$10,000 and shares are held by the instructors. It is not licensed under the Regents. It is organized under the laws of Delaware and its agent in this state is an attorney who lives in Far Rockaway, and is a shareholder in the school. The commencement exercises of the school are held in New York City but the diplomas are issued from the office in Wilmington, Delaware. Dr. Hirschland said that the constitution of New York required the recognition of degrees issued in another state and in this way he justified the evasion of issuing the diplomas in another state.

As to educational qualifications, the witness said that a high school education or its equivalent was necessary, but that his school determined what that equivalent was. He said that a chiropractor in actual practice should be given the right to continue just as the physicians in practice in 1892 were allowed to continue. He did not believe in correspondence courses at all.

The next witness, also the last, was Mr. Vernon Baker of Tannersville, Greene County, N. Y., a Justice of the Peace and auto dealer. He was not a chiropractor but had been treated by a chiropractor.

His first treatment was received nine years ago after being struck by an automobile. He sent for his doctor, but got no better for a day or two, and then a commercial traveller induced him to consult a chiropractor in Kingston and in three days he was entirely well.

Then Mrs. Baker fell down stairs and had gall stones, and was nigh unto death, being kept alive by arsenic and strychnine. An operation was suggested and was refused. The Kingston chiropractor said she was a simple case of gall stones and that he could cure her. He gave her an adjustment and that evening she belched wind six times and was well on the road to recovery.

Next Mr. Baker went deaf following a dose of medicine and a doctor said he would be at least five years getting well. The chiropractor cured him in two weeks.

Mr. Baker's further experience followed a little supper of roast beef and beans and the next morning he lay on the floor with colic. During the next three days a doctor gave him two doses of castor oil, six cascaraes and nine doses of ex-lax without result. On the fourth day he went to his chiropractor who gave him three adjustments an hour apart and after the last he went to the bathroom and was relieved. He said that when he went home his doctor asked him "Why did you not wait until you were cured before you went to the chiropractor?"

The last experience that he related was that of his daughter who fell when she was four years old and had a deformed leg ever since. The chiropractor straightened the leg and helped her to walk.

The committee will hold other hearings of which due notice will be given. The hearings will be reported in this JOURNAL in order that the members of the Medical Society of the State of New York may be informed of the claims of chiropractors and may prepare themselves to answer their arguments.

## ART EXHIBIT

An exhibition of works of art done by physicians will be held in the New York Academy of Medicine, Fifth Avenue and 103d Street, New York City during the first two weeks of next March. Specimens are solicited from physicians living in any part of New York State. Among

the articles desired are paintings, etchings, sculptures, photographs, wood engravings, book binding, and any other work of art suitable for exhibition purposes. Sixteen physicians have already entered exhibits. For information address the New York Academy of Medicine.

system continues to increase, showing that the organization and work of the laboratory have received world-wide recognition

### MEDICAL PRACTICE ACT

A most important step in the promotion of health was taken last Winter in the revision of the Medical Practice act. The annual re-registration of licensed physicians will facilitate the discovery of those who are practicing medicine, though not licensed so to do. The prosecution of such persons is made easier. It also establishes a grievance committee of physicians, which will examine into complaints against licensed physicians and report to the Board of Regents what action should, in its judgment, be taken. Some time must necessarily elapse before these new and important provisions can be fully carried into effect and the public benefits therefrom be fully realized. They should go very far toward bringing about a condition of affairs in which any person suffering from accident or sudden illness, in any part of the State of New York, and seeking the services of a physician, can be assured that he is not falling into the hands of a person lacking the essential requirements of medical education.

New York State leads in its conception that protection of the public health is a primary function of the State. It is on that theory that we have established our several forms of State aid to local efforts in this direction. I bespeak your continued cooperation with this department and a continuance of liberal appropriations for its work.

### DEPARTMENT MENTAL HYGIENE

On the whole question of the care of the mentally afflicted I propose to communicate with you much more fully at a later date, and at that time I will set forth the exact condition at all of the State hospitals, showing in detail improvements made as a result of the expenditure of the money received from the sale of bonds. For the purpose of this message I will deal only with the progress made in care and prevention.

The establishment of a unified department of mental hygiene to exercise the functions of the present State Hospital Commission and State Commission for Mental Defectives and to supervise the care of epileptics is a great forward step. The State thus recognizes the fact that the institutional care of the mentally afflicted is a single problem and that progress will be facilitated by union of effort. A high standard of care of patients has already been reached by the institutions brought together in the new department, but it is believed that through free interchange of ideas the various institutions will be mutually helpful in the solution of their many problems.

The establishment of a division of prevention in the new Department of Mental Hygiene com-

mits the State to a new policy with respect to mental defectives. Heretofore the State has provided generously for the care and treatment of the mental patients sent to institutions, but has done comparatively little to prevent the development of mental disease in the community. No one can predict the possibilities of preventive work in this field, but from the marvelous results that have been accomplished in the prevention of physical disease, we may confidently hope that the influx of patients in the State hospitals may be checked and that the heavy burdens thereby imposed on the people of the State may be lessened.

Judging from the experience gained in the prevention of physical diseases, three major lines of activity are indicated in the field of mental hygiene. Research work should be conducted on a more comprehensive scale. Preparations to do this are being made by the erection of a large psychiatric institute and hospital to form a part of the new medical centre in New York City. Now that this main institution of the State hospital system in New York City is about to take form, I would recommend the development of one or more similar institutions of smaller size in strategic centres up-State, particularly in cities where medical schools are located.

Last Winter I approved a bill which authorized the construction of a State psychiatric hospital in Syracuse in connection with the university medical centre there, as soon as funds are available for construction. I urge that an appropriation for the construction of this institution be made available this Winter in order that an up-State centre for early treatment and teaching purposes may shortly follow that in New York City. The studies carried on in these centres should be supplemented by field work and by researches in the State hospitals and other institutions. The field is broad and research work therein difficult, but every means must be taken to discover more effectual methods of relieving the mentally afflicted and of preventing the development of mental disorders.

The clinics conducted by the State hospitals for the early treatment of persons suffering from mild nervous and mental disorders, and to aid in the adjustment to community life of paroled and discharged patients, have proved of great value, and should be extended so as to become more effective preventive agencies. Thus far the clinics have dealt principally with adults. Children manifesting marked behavior disorders should also be reached. This could best be done by the establishment of permanent child guidance clinics in the principal cities of the State.

Marked progress has been made in the development of occupational treatment of patients in the State hospitals. At the close of the fiscal year the number of patients receiving occupational

knowledge, the decrease in illness and deaths has been for the most part extremely satisfactory, although the general death rate among the people of the State in 1926 shows a fractional increase over that of the previous year, due almost entirely to higher mortality from influenza, pneumonia, diseases of the heart and cancer

The soundness of the slogan of our Health Department that within natural limits public health is purchasable has so far been demonstrated by the record

The campaign against diphtheria, inaugurated by the State Department of Health and cooperated in by the general medical profession, unofficial health agencies and insurance companies, is already showing notable results. In 1888 diphtheria killed 6,500 persons in the State of New York while the total for 1926 will be under 700, much the lowest death rate ever attained. It may be expected that with the continued cooperation of all agencies and the people at large, diphtheria, not long ago one of the scourges of childhood, will be eradicated from the State

Scarf fever has almost ceased to be a factor in childhood mortality. The tuberculosis death rate during the past year reached a new low mark, being less than half the rate of twenty years ago

It is most gratifying to note that the increased funds afforded to the work of prevention of maternal and infant mortality are producing favorable results. The mortality among women from septic poisoning in childbirth was lower in 1926 than ever before, and there is every hope that we are approaching a time when childbirth will no longer hold any risk of avoidable infection

Strange to say, that while the death rate from preventable diseases here mentioned is constantly on the decrease, deaths from alcoholism have increased fivefold between 1920 and 1926, a condition, I am informed by our Department of Health, which is prevalent in all parts of the country. Surely this is a preventable disease and one most difficult for a Department of Health to deal with

Under existing law a county is permitted to constitute itself a general health district with its own health officer, personnel and budget. This amendment was made to the Public Health law as far back as 1921 upon the recommendation of the late Health Commissioner, Dr Hermann M Biggs. It is a matter of history that he was deeply concerned about it and had an unshakable faith in the advantages to the public health that would result from the establishment of larger health units on a county basis. It is regrettable that in the time that has elapsed since the enactment of the statute only one county in the State has taken advantage of it

I most earnestly recommend that this system of health organization be tried by other counties. In order to make an effort to bring to the atten-

tion of Boards of Supervisors the benefits that accrue from this form of organization, I propose during the Winter, in conjunction with private health agencies and our own State Health Department, to hold a conference on this subject in Albany

#### STATE AID TO COMMUNITIES

The law which grants State aid to rural communities for public health work has worked out in an extremely satisfactory way. Up to the present time twenty-four counties have taken advantage of it largely for the purpose of providing county public health nurses. Thus at a comparatively small cost to the State and county a very promising beginning has been made in providing a much-needed service to rural counties

The Legislature, by enacting laws providing for the physical care, education and welfare of physically handicapped children, has very wisely placed the major responsibility upon local public agencies, providing at the same time for State financial aid

The Judge of a Children's Court may now issue an order for the care, treatment or education of a crippled child, fixing the amount to be expended and the part of the expense, if any to be borne by the parent or guardian. When this order has received the official approval which the law requires, the balance of the expense becomes a county charge, the county being entitled to partial reimbursement by the State

Administration of this important activity is vested in a bureau in the State Department of Education cooperating with the State Department of Health. The number of court orders already issued indicates a growing appreciation of the needs of this class of unfortunate children and of the wisdom of assisting them to become self-supporting citizens. I recommend that this work be continued and, so far as possible, extended

Another provision for State aid to public health efforts permits the various districts of the State to secure a local laboratory service equivalent in scope and standards of work to that of the central State laboratories. Nowhere else is there to be found such a completely organized, coordinated and cooperating system of public health laboratory service as is now developing in New York State. There are now 106 approved laboratories. Of these, 22 are functioning under State aid serving 14 counties and the large centres of population in 4 additional counties, and at least 4 more counties have laboratory service under consideration

With the allotment from the bond issues, the State laboratory will be able to complete its program of building started ten years ago. With these improved facilities the public health laboratory service of the State will be unequalled. The number of visitors from other States and foreign countries who come here to study our laboratory

fect during the meeting. The hotels on this list are members of the Hotel Association at Niagara Falls and can be depended upon as being absolutely as represented.

Reservations should be made direct with the hotel. If for any reason you desire information regarding hotels other than given here, please address Dr. George L. Miller, Chairman of the Committee on Hotels, Chamber of Commerce Building, Niagara Falls, New York.

In later issues of the Journal, the Committee on Arrangements will endeavor to give further information and details concerning points of arrangements, such as, transportation, touring information, garages, etc. For the present, will you not please take advantage of the above information and make your hotel reservation early?

FREDERICK J. SCHNELL, M.D.  
Chairman, Committee on Arrangements

### DINNER TO DR. WENDELL C. PHILLIPS

A dinner in honor of Dr. Wendell C. Phillips, President of the American Medical Association, will be held on the evening of Thursday, January 27, in the Waldorf-Astoria Hotel, New York City, under the auspices of the Medical Society of the State of New York. The dinner was authorized by the Council at its last meeting, and the following committee of arrangements was appointed: Drs. N. B. Van Etten, Chairman, D. S. Dougherty, O. S. Wightman, W. H. Ross and John Jennings.

The dinner is a recognition of the advancement of a physician of New York State to the leadership of the national medical society. Dr. Phillips has served as president of the New York County Medical Society and the Medical Society of the State of New York, and has retained his activities in both societies, although his national office makes heavy demands on his time. A record of his activities would constitute a history of organized medicine in New York State for the past forty years.

The committee of arrangements have planned that groups of doctors may reserve their own tables. The ladies will be made welcome. Tick-

ets are six dollars each. A reception to Dr. and Mrs. Phillips will be held at 7 o'clock, and dinner will be served half an hour later.

Dr. George M. Fisher, President of the Medical Society of the State of New York, will preside. The speakers will include Reverend Dr. Harry Emerson Fosdick, Dr. Frank Billings of Chicago, Dr. George David Stewart, President of the American College of Surgeons, and Dr. Samuel Lambert, President of the New York Academy of Medicine.

Since this is an official event, there should be a large attendance from all parts of New York State. Letters have been sent to the officers of all the county societies and responses are already being received.

Among the organizations which will be represented is the League for the Hard of Hearing, which will have several tables specially wired, so that the deaf members may hear the speeches. The members of this organization are especially desirous of honoring Dr. Phillips because he was the founder of the American Federation of Organizations for the Hard of Hearing.

---

### WAYNE COUNTY

The following account was clipped from the *Lyons Republican* of December 14:

The Wayne County Medical Society, at a recent meeting at the Court House in the Village of Lyons, elected new officers for the ensuing year. The officers elected are as follows: President, Dr. William H. Sweeting of Savannah, vice-president, Dr. Frederick W. Andrews of Sodus, secretary and treasurer, Dr. Dewight J. Johnson of Newark.

An interesting program was rendered and the meeting was one of the largest and best attended

meetings held in the history of the association. Dr. Alfred K. Bates of Auburn and Dr. R. R. Finch of Rochester were the principal speakers from outside of the county. Many members of the association took part in the general discussion which took place and the meeting proved to be a most interesting and profitable one.

Dr. William H. Sweeting, who is president of the Society, is a son of the late Dr. Mortimer F. Sweeting of South Butler, who in his day was one of the most prominent citizens in eastern Wayne, both in the field of medicine and in politics.

therapy in special classes was 11,379, as compared with 9,848 at the end of the previous year. This treatment, which is conducted by trained occupational therapists and physical instructors under the supervision of the medical staff, is proving of inestimable benefit to the patients.

### CHILD WELFARE

Our great State has abundant reason to be proud of achievements in the field of child welfare and especially of our care of orphan children. We are in the very front of the commonwealths of the country in safeguarding the rights of children and preserving home life when the

family has been deprived of the provider by death.

To my mind, however, there remains one important thing to be done and that is encouragement to the localities to establish child welfare agencies by a State subsidy for the care of widows and orphan children. I recommend that State appropriation be made directly to each organized board of child welfare of an amount equivalent to that annually appropriated by local authority. This suggestion has for its purpose not only aid to the locality, but is intended to furnish encouragement to the localities that have not yet made ample and sufficient appropriation for this very worthy object.

### THE ANNUAL MEETING

The Annual Meeting of the Medical Society of the State of New York will be held at Niagara Falls, May ninth, tenth, eleventh, and twelfth.

The House of Delegates convenes on Monday, May 9th. The scientific sessions begin on Tuesday afternoon, May 10th, and continue

as interesting and as broad as was that on syphilis last year. When you make arrangements for attending the meeting, please arrange to stay for Thursday.

The Committee on Arrangements is looking for a record attendance at the Annual Meeting and arrangements are being made accordingly. At

### ROOM RATES

#### NIAGARA FALLS, NEW YORK

Names and Location	Persons Capacity	Room One Person		Room Two Persons	
		With Bath	Without Bath	With Bath	Without Bath
Hotel Beirs, 109 Falls Street	211	\$2.50	\$2.00	\$3.50	\$3.00

\*Season May 15th to September 22nd

°American Plan

Wednesday and Thursday. Thursday will be devoted entirely to the study of cancer. There will be demonstrations, clinics, and lectures.

The program for cancer day is being arranged by a special committee of the Committee on Scientific Work, of which Dr. Burton T. Simpson of Buffalo, Director of the State Institute for the Study of Malignant Diseases, is the Chairman. The subject will be presented in a manner

the season of the annual meeting. Niagara Falls will appear at its best. This meeting will therefore provide not only an opportunity of listening to a very interesting scientific program, but also an opportunity to have a few delightful days of respite from routine professional cares.

There follows a list of hotels at Niagara Falls, with accommodations and rates. These are regular prevailing rates and the same will be in ef-

from alcoholism are caused by the wood alcohol or other poisons besides ethyl alcohol. If murder, or suicide, or just plain death follows the drinking of this liquor, who is guilty, the Government official who denatures the alcohol, the bootlegger who sells it, or the person who buys and drinks it?

Then, too, another complication rises. It is well known that any alcoholic liquor recently distilled is poisonous. Would a large number of cases of poisoning develop if the liquor was distilled from fermented grain?

The fact is that no scientific basis or standard has been developed or put into general practice by which the truth regarding the deaths can be ascertained. It would seem that out of the millions of dollars appropriated for prohibition enforcement, a good sum, say one million dollars, could wisely be given to some medical laboratory to be used in the investigation and publication of the facts regarding alcoholism.

According to the *New York Times* of December 30, two newer denaturing formulas proposed by the United States Government are as follows:

"Effective January 1, 1927. Completely Denatured Alcohol Formula 5 will be compounded according to either one of the following formulas. After April 1, 1927, it will be compounded only according to the first one of the stated formulas.

#### OPTION 1

"100 parts by volume ethyl alcohol, not less than 160 degrees proof

"48 parts by volume approved methanol (denaturing grade)

"0.75 parts by volume of the compound or one similar thereto known as aldehyd grade A

"0.5 parts by volume approved benzene (kerosene)

#### OPTION 2

"100 parts by volume ethyl alcohol, not less than 160 degrees proof

"4 parts by volume approved methanol (denaturing grade)

"2.25 parts by volume approved pyridine bases

"0.25 parts by volume approved pyridine (kerosene)"

The problem of denatured alcohol is further complicated by its relation to manufacturing. The *New York Herald Tribune* of January 5, says:

"The Industrial Alcohol Manufacturers' Association has been seeking a suitable denaturant, less poisonous than wood alcohol, in cooperation with the chemists and scientists of

the Mellon Institute at Pittsburgh for the last three months, but the problem has not yet been solved.

"Swollen hands, partial suffocation, headaches and often severe affections of the eyes trouble the workmen and women who have to handle denatured alcohol treated with raw wood alcohol, it was said yesterday by Mr. Landes, attorney for several industrial alcohol manufacturers and users. Numerous cases of such poisoning have been brought to the attention of the Workmen's Compensation Bureau, he said, and labor generally should recognize the dangers that will ensue if the government succeeds in its efforts to make raw wood alcohol virtually the universal denaturant. The effects of methyl alcohol were not so severe, he said. Many manufacturers of varnishes, lacquers, stains, polishes, disinfectants and liquid soaps, among other industrial alcohol products, would be driven out of business or crippled by lack of proper workmen, it was said, if forced to use wood alcohol instead of the refined methyl alcohol."

Practically every substance used as denaturants is a poison, as also is ethyl alcohol. Other solvents besides the alcohols are used in manufacturing, such as carbon disulphide and banana oil, and most of them poisonous both externally and internally. The solvents used in manufacturing are fairly well standardized, their effects are known, and precautions are taken against their harmful effects. Manufacturers who employ thousands of workmen, and who have adopted precautions against the poisonous effects of solvents, are vitally interested in the proposals to change the denaturants used in alcohol. The welfare of thousands of workmen is quite as vital as that of the drinkers who take long chances in buying liquor.

This JOURNAL in its last issue commented editorially on tests for alcoholic intoxication, and called attention to the lack of accurate scientific data concerning the effect of ethyl alcohol when used as a drink. Equally unsatisfactory are the data concerning the effects of the denaturants upon the body both internally and externally.

The glaring headlines on "Poison Alcohol" that appear in the daily newspapers, and the columns of matter that are printed on the subject might lead the readers to conclude that an entirely new element had been injected into the drink problem. But the fact is that the pathological effects of both alcohol and its denaturants have been known *qualitatively* for years. What is needed is research which shall determine those effects *quantitatively*.

# THE DAILY PRESS

## POISON ALCOHOL

The daily papers have recently been carrying big headlines asserting that poisons in alcohol are the immediate cause of numerous deaths from alcoholism during the holiday season. The *New York Sun* for Thursday, December 30, says

"Poison holiday liquor yesterday took four more lives in New York City, bringing the toll since Saturday to 34, for the month to 64, and for the year to 758, a record for all time. Indignant protests against the policy of the Government in poisoning alcohol poured in from prominent citizens and officials. Medical authorities gave out figures of the alarming increase in the number of deaths from alcoholism since prohibition was adopted.

"That the wave of death from bad whisky and gin has not abated is shown by the reception at Bellevue Hospital last night of fifteen more cases of acute alcoholism, making a total of 125 persons treated there this week.

"In many cases where death results from alcoholism, if there is complication from pneumonia or heart disease, the family physician, according to health authorities, will give one of the latter causes in his report to save relatives of the dead man from what they might consider shame. For this reason the total of deaths from liquor poisonings is never known, not even approximately. Officials admit that it may easily run into thousands a year."

The question arises, are the deaths caused by poisons added to the alcohol, or are they due to the ordinary ethyl alcohol which is the essential component of all alcoholic drinks? On this subject, Dr. Louis J. Harris, Commissioner of Health of New York City, is quoted in the *New York Herald Tribune* of January 5, as saying

"A grand total of about 430 alcoholic cases of all kinds treated in hospitals throughout the city during the period between Christmas Eve and yesterday had been reported last night to Health Commissioner Harris, who is making a survey of the situation at the suggestion of Mayor Walker. Of these considerably more than half were treated at Bellevue, where ten new sufferers from alcoholism were admitted yesterday. No deaths were reported during the day.

"Dr. Harris, commenting on the hospital reports, said that his survey showed 'neither an unusual number of cases of alcoholism in the city hospitals nor unusual poisoning from alcohol

"There was considerable acute sickness as the result of excessive drinking, as there has been during holiday periods in the past,' he said.

"But I see no reason for any alarm about poison alcohol. I see nothing in the situation calling for specific action on my part at this time. There is as much liquor flowing freely, apparently, as when there was no prohibition law, and that is the most important lesson to be derived from our survey."

In contrast with this opinion of a physician formed after an investigation, is the opinion of a noted educator whom the *New York Herald Tribune*, of December 30, quotes as follows:

"Murder! Just plain, unadulterated murder by our glorious, paternal government, is what I think of the deaths attributed to consumption of liquor manufactured from poisoned alcohol," exclaimed Dr. Nicholas Murray Butler, president of Columbia University, at his home, 60 Morningside Drive, last night.

And there is also the following opinion of Wayne B. Wheeler, General Counsel of the Anti-Saloon League, which is quoted in the same paper with Dr. Butler's opinion:

"The Government," said Mr. Wheeler, "is under no obligation to furnish the people with alcohol that is drinkable when the Constitution prohibits it. The person who drinks this industrial alcohol is a deliberate suicide."

There are thus three conflicting theories regarding the recent deaths from alcoholism, and the newspapers give by far the greatest publicity to the poison theory, meaning a poison added to the drink. The scientific literature available on the subject is meagre, and physicians as well as laymen have to depend on the items in the daily newspapers for information. The *New York Times* made an effort to obtain the facts regarding the poisons contained in alcoholic drinks.

It is common knowledge that the poisons consist of substances added to alcohol in order to "denature" it, or render it obnoxious for human consumption. The substance most commonly used is wood alcohol. Denatured alcohol has been extensively made and used over all the world for at least a quarter of a century, but with the recent increase in bootlegging in the United States, anything containing alcohol is distilled and the product is sold for drinking purposes. A liquor distilled from denatured alcohol will contain some of the denaturing substance, and many of the deaths

## The Management of an Infant's Diet

# Malnutrition, Marasmus, Infantile Atrophy, Athrepsia

In an endeavor to improve conditions that may be properly grouped under the above mentioned terms, the first thought of the attending physician is an immediate gain in weight, and the second thought is to so arrange the diet that this initial gain will be sustained and progressive gain be established. Every few ounces gained means progress not only in the upward swing of the weight curve, but in digestive capacity in thus clearing the way for an increasing intake of food material. As a starting point to carry out this entirely rational idea, the following formula is suggested:

Mellin's Food	8 level tablespoonfuls
Skimmed Milk	9 fluid ounces
Water	15 ounces

This mixture furnishes over 56 grams of carbohydrates in a form readily assimilated and thus quickly available for creating and sustaining heat and energy. The mixture supplies over 15 grams of proteins for depleted tissues and new growth, together with over 4 grams of inorganic elements which are necessary in all metabolic processes. These food elements are to be increased in quantity and in amount of intake as rapidly as continued improvement is shown and ability to take additional nourishment is indicated. Suggestions for this readjustment are set forth in a clear manner in a pamphlet devoted exclusively to the subject, which will be sent to physicians upon their request.

Continued repetition of highly successful and oftentimes remarkable results from the application of this procedure justifies its universal recognition.

Mellin's Food Co., 177 State Street Boston, Mass

## THE ENDOWMENT FOUNDATION OF THE MICHIGAN STATE MEDICAL SOCIETY

The Michigan State Medical Society has accepted funds for the purpose of promoting graduate education and has appointed the Grand Rapids Trust Company as trustee of the fund. Regarding the endowment the Journal of the Society for January says:

"Funds are necessary for our educational work. The increase of society dues is inadvisable. Consequently needed monies will be forthcoming from this foundation. As such monies become available our educational program will be broadened in scope and extent. The Council is now giving careful consideration to the creation of an all-year Michigan Post-Graduate Medical school. It is purposed also to send competent instructors to County Societies for one or two-day programs. We are alert to the need of the day and are seeking to formulate permanent plans

that will supply those needs and serve the best interests of our members.

"Two bequests have already been made to the foundation. We are seeking others. We want and require an endowment of not less than \$250,000. We believe that it is considerate to suggest, yes urge, that those who are able, should now tender additional bequests. Some may also desire to incorporate such a provision in their wills. It must be apparent that monies so bequeathed will provide funds in perpetuity for our profession. But more in that regard will be imparted in a future issue. This statement acquaints you with a plan that has resulted from much thought and labor. It also imparts the broadening scope of your society's endeavor giving added reason for membership affiliation."

## DIAMOND JUBILEE OF THE IOWA STATE MEDICAL SOCIETY

*The Journal of the Iowa State Medical Society* for December contains an article entitled "The Diamond Jubilee," which recounts the historical facts regarding the practice of Medicine in the State of Iowa. The following extracts are taken from the article:

"That uncultivated prairie which later was named Iowa was first visited by the white man in the summer of 1673, two hundred and fifty-three years ago, when two brave Frenchmen, the woodsman Louis Joliet, and the missionary Jacques Marquette, skirted the eastern shore of Iowa on their momentous voyage of discovery.

"Dr Isaac Galland with his family settled on the west shore of the Mississippi in 1829, at a point called At-Wip-E-Tuck, afterward known as Nashville. Doctor Galland hoped to build a city here, but Keokuk became too strong a competitor.

"One of our past presidents, the late Dr C F Wahrer of Ft Madison, has left some interesting data regarding this versatile and picturesque character of Iowa pioneer physicians. It was said of him that he was a brilliant physician and was specially successful in the treatment of cholera, as well as the prevention of the epidemic. One of his contributions was a medicine chest or box about one foot cubic, on which was printed in red letters, 'Dr Isaac Galland's Family Medicines.' This box contained the usual and ordinary remedies used by

the doctors in those days, and was placed in nearly every cabin in his wide field of practice. This no doubt was very helpful as physician and drugs were scarce. He evidently did not practice all of the time, but was engaged in many other pursuits. In 1830 he established the second newspaper published in Iowa called 'The Western Adventure.' Two years later the paper was sold and the name changed to 'Madison Patriot.' In the columns of this paper he left a description of the prairies and waters of Iowa, its animals, serpents, birds, plants and Indian life and habits, which showed him to be an able writer and historian. He also wrote a history of Iowa, made a map of Iowa, and in 1840 wrote a book, 'The Iowa Immigrant.'

"For a time he lived across the river in Illinois, and while there was very active as a Methodist elder, being the private secretary of Prophet Joseph Smith in the Nauvoo settlement, but when Prophet Smith lost prestige and his power waned in Nauvoo, Doctor Galland left the church. He practiced at various times in Nashville, and Galland, Montrose and Ft Madison, where he died in 1858.

"In this and in numerous other instances, it will be seen that men educated as physicians had much to do with the development of the state. They brought with them the beginning of general culture, and by reason of the culture

(Continued on page 98, adv. sec.)

character. Success in those days meant a degree of personal sacrifice, courage and determination not ordinarily seen, and what success and reputation was finally secured was well earned. Doctors under these conditions became resourceful and self-reliant, and were able to meet emergencies to a degree rarely seen today. There was little opportunity for contribution to medical science, and there seems to have been little disposition to record 'interesting cases' or 'personal experience,' unless they were of real interest. Their work was rather a silent influence, that contributed to the general betterment of a community and of which very little has been recorded. The name of the doctor often remains only as a tradition.

"In 1850 nearly one-half of the physicians practicing in Iowa were not medical graduates. The men who had not attended a regular medical school were often not familiar with a code of ethics save one that would bring practical results. While these were disturbing elements never-the-less, a liberal spirit on the better part of the physicians led to the belief that society fellowship would inspire better feeling and to possible higher qualifications.

"When the twenty-five Iowa pioneer practitioners of medicine met at Burlington, Iowa, in June, 1850, for the purpose of organizing a state medical society, it was in response to a firm belief in the minds of a few broad-minded physicians, with a view to the future, that organized medicine was the only means of progress, and towards higher educational standards, with greater benefits to the state and the people generally.

"The inspiring genius of the memorable occasion and father of the Iowa State Medical Society was Dr. John F. Sanford of Farmington, and later of Keokuk. He had attended a meeting of the American Medical Association in Boston in May, 1849, when an appeal was made for all states to organize state and county societies. This made such a profound impression upon Doctor Sanford, that on his return home he wrote many letters to physicians urging them to meet in Burlington the coming May for the purpose of organizing the Iowa State Medical Society. Feeling that sufficient interest would not be aroused by correspondence alone, he concluded to make a personal appeal, and went by stage to Keosauqua, Fairfield, Mt. Pleasant, Washington and Davenport, a distance of nearly 200 miles and then by steamer to Muscatine and Burlington, Ft. Madison and Keokuk, spending a day in each town, calling upon the physicians and urging their cooperation in this new movement. As a result twenty-five physicians gathered at the court room in Burlington, June 19, 1850, for the purpose of organizing a State Medical Society, Dr. John F. Sanford

# NOW— FOR BETTER SERVICE

More than 38,000 physicians practice within 250 miles of our store. More than one-fourth of the total number of registered physicians in the United States are within the zone of immediate service from one of the most complete and one of the best equipped retail stores in New York City. More than one-fourth can buy cheaply, easily and quickly from this great service station of a world-wide organization.

## INCREASING DEMAND

It is not at all surprising that the service offered in our New York Store has brought in a gradually increasing business so that we quickly found ourselves short of space.

Hospitals, physicians and dentists in New York and vicinity have discovered the advantages of buying from us in New York. To our original building we added warehouse space, but this was not enough. It was necessary to do more, to find a new and larger store that we might further improve our service and take care of our ever-increasing business.

An extensive study of subway and "L" express stops, through crosstown streets, railroad terminals and parking facilities, helped us to decide upon our new and larger store at 348-350-352 West 34th Street. You will find it easy to reach and the service there will please you.

vated power of observation, freedom from prejudice and superstition, and knowledge of the dangers surrounding the early settler, made the doctor peculiarly fitted to aid in the pioneer work of the settlement.

"Probably the first real pioneer physician to locate in Iowa was Dr. Frederick Andros, who came to Dubuque in 1833 for the distinct purpose of practicing medicine. He was a native of Massachusetts, a graduate from the literary department of Brown University in 1822, and from the medical department in 1826, coming to Dubuque seven years later.

"The late Dr. Henry H. Clark of McGregor was associated with Doctor Andros during the ten years from 1870 to 1880, and in an address before the State Society in 1916 gave some interesting reminiscences of this first physician of Iowa. Doctor Andros was evidently far superior in intelligence and ability to the average physician of his day, but at the same time he was a typical frontiersman and something of a character. Dr. Clark related this story which will bear repeating—"I remember a country drive I took with him a short time after I came to McGregor. He drove a good horse, but he interfered so badly that either his right or left hind leg seemed to be in the air most of the time. As we were jolting over a rough road back in the Mississippi hills, the Doctor suddenly stopped his horse with the remark—"There's the damndest nicest spring over there I ever saw." We got out and walked over to where a fine stream of water gushed from the rocks and formed a pool about three feet in diameter and eighteen inches deep. The Doctor took off his high silk hat, which he always wore and in which he carried his letters, red bandanna, cigars, stethoscope, and always either a clean or dirty collar, pulled off his coat, rolled his sleeve to the elbow and thrust his hand to the bottom of the spring. After lifting aside a few stones, he pulled out a flask of whiskey, uncorked it, took a generous drink and then returned the bottle to the bottom of the spring for future use.

"In 1880 when he was eighty years old he decided that Iowa was getting too civilized and tame, and went west 'to grow up with the country.' He practiced in Dakota for ten years, after which he changed his residence to Minneapolis where he died at the age of ninety-one years.

"It was a fine group of notable practitioners of medicine who located in Iowa before the year 1850. Very few came any farther west than Oskaloosa. Iowa appeared a fruitful field for the young practitioner with ambition to succeed in many ways. It thus happened that many pioneer settlements secured medical practitioners of a selected class, men of strength, courage and

## SCIENTIFIC SERVICE COMMITTEE

The Illinois Medical Journal for December records the establishment of a committee on Scientific Service for county medical societies on September 1, 1926, by the Illinois State Medical Society. The object is to provide scientific programs for the county societies along the lines of medicine surgery, obstetrics, gynecology, orthopedics, pediatrics, mental hygiene, and eye, ear nose and throat. Twenty-seven counties have already made use of the service.

The committee has established a Scientific Speakers Bureau and prints the following practical suggestions for those who want to conduct the programs:

"The Scientific Service Committee plans to institute a service for members of county medical societies which shall be conducted from the point of view of the consultant rather than of the teacher. The whole point and purpose is to bring to the general practitioner specific helps for his daily practice. For the attainment of this purpose the following suggestions should be borne in mind:

1 The paper should be non-academic. Be concrete, practical and specific in your remarks.

2 The history and bibliography of a given subject should occupy a relatively small proportion of the paper.

3 Talk to your audience as man to man. Many an excellent paper delivered in a patronizing manner has antagonized the audience and wasted the time of the essayist.

4 Remember that attention can be concentrated upon you and your subject in inverse proportion to the size of the audience. Every effort will be made by the committee to obtain appointments for speakers in larger towns where accommodations are better and audiences substantial, as well as in the smaller communities in which there is, perhaps, the great-

est demand for this service. But from the point of view of personal appreciation, the essayist will do well to bring his best to the small audience.

5 Talk clearly and directly. The effective speaker before a lay audience is also the effective speaker before the scientific audience. Doctors are made of the same clay as other folks—subject to the same likes and dislikes. Of two papers equally valuable, they will prefer the one whose speaker they can hear distinctly, who is familiar enough with his subject to get away from his paper frequently, who seems equally as interested in their comments on his ideas as he is in getting his own ideas across.

6 The test, then, of the best paper for the purpose of this committee is that it is practical, that it is presented clearly and simply, that it stimulates and invites discussion. It is better to start folks thinking for themselves along a given line than to give them ready-made thoughts and arbitrary judgments."

These standards will apply to the speakers before any society. Why should it be necessary to emphasize them? The answer is that our colleges do not train their students in public speaking. Yet ease in expressing one's self in public is easy to acquire, as is demonstrated by the development of the art by uneducated and inexperienced men who study to carry out the rituals of lodges.

Making up a program for a county medical society requires considerable thought and planning. The program maker must know his fellow members, their attainments and limitations, and he must know the peculiar traits of the speakers whom he secures. Programs are often hurriedly arranged by those who know neither the audience nor the speakers. The Illinois plan insures a good speaker for every meeting, and he can adapt himself to any audience. Medical education would be greatly promoted if these suggestions were followed.

# SALIPYRIN *Riedel*

Is a chemical combination of antipyrin and salicylic acid. The therapeutic effects of both these components are preserved, although modified by close chemical union and in a very great degree deprived of the dangers of mechanical mixtures.

Salipyrin is distinguished from other salicylates

by the comparative freedom from ill-effects (absence of free antipyrin) and prompt antipyretic and sedative action

**INDICATIONS** Influenza, Colds, Catarrh of the Nose and Throat, Rheumatism, Neuralgia, Alcoholic Excess, Pleurisy, Dysmenorrhea, Metrorrhagia, Vaginitis, etc. If given early in the attack, Salipyrin generally succeeds in aborting colds

Salipyrin is supplied in powder form and as SALIPYRETS in tablets of  $7\frac{1}{2}$  to 15 grains each.

Approved by the Council on Pharmacy and Chemistry of the American Medical Association for inclusion with N. N. R.

**RIEDEL & CO., Inc.**

## The Robertson Super Therapeutic Lamp

The ultimate in Radiant Light and Heat Apparatus. Instantly adjustable in every desirable treatment position. Counter-balanced stand. Beautifully finished—shipped completely assembled

**\$130.00**

Either 1000 or 1500 Watt Therapeutic Blue or Clear Bulb and Boric Glass Protective Screen.

Also made in two other floor, ceiling suspension and wall bracket types

**LEO F. ROBERTSON, Inc.**

534 West 22nd Street New York  
Inquiries promptly referred to our representative

acting as temporary chairman and Dr E D Ransom as temporary secretary

"It was resolved that the first meeting of the Society be held at Fairfield, Jefferson County, on the first Wednesday in May, 1851. On the following day, June 20, 1850, the *Burlington Weekly Telegraph*, forerunner of the *Hawkeye*, referred to the organization meeting, in part as follows: 'The convention is eminently respectable in appearance, and anyone would see at a glance that it embraces among its members all the learning known to the profession, and the numerous and able speeches made by various members during the debates of yesterday evinced a high degree of talent. Indeed, taken as a whole, it is perhaps the most respectable convention which has ever assembled in our state. There are many gray beards among them, who while adding dignity and weight of character to the convention, also give tone and direction to the proceedings'

"At the first regular meeting of the Iowa State Medical Society in Fairfield in May, 1851, Doctor Sanford presented an interesting report on the 'Causes Which Contribute to Depress the Science and Dignity of the Medical Profession of Iowa.' From this address we quote as follows: 'Some of the most prolific causes of this unhappy condition in the profession are due to the want of preliminary education in those who have entered the profession. A better preliminary education on the part of our medical students will do more to improve and maintain the honor and dignity of the profession than any arbitrary exactions of medical colleges or society or proscriptive legislative enactment. The establishment of numerous literary institutions in Iowa will doubtless display its influence in the ranks of the profession. The second cause which tends to lower the estimation of the profession in the minds of the public refers to the influence of ignorance among the profession themselves'

"The organization of county societies kept pace with the growth and progress of the State Society. The first society so designated was the Polk County Medical Society which was organized October 24, 1851, so that it also will be entitled to a diamond jubilee celebration in the near future. The Keokuk Medical Society was organized October 3, 1850, but the society was limited to Keokuk city, and did not include Lee county, but it is fair to assume, however, that this was the nucleus of a county society

"The influence of our State Society upon the progress and development of medical schools and education would form a theme by itself. It is interesting to note the intimate relation of the work of the society to the progress of medical education, throughout its entire existence."

## SUPERNUMERARY URETERS WITH EXTRAVESICAL OPENINGS\*

By H DAWSON FURNISS, M D, F A C S, NEW YORK, N Y

THE fact that in my own practice I have seen 30 patients with three ureters and one with four would prove that supernumerary ureters are not uncommon, on the other hand, that in only three of these 30 cases did the ureters have extravasical openings would show that this latter anomaly is comparatively rare

When I reported my first case in 1914, I could find records of only 50 others. In the January, 1926, issue of *Surgery, Gynecology and Obstetrics*, Kilbane brings the literature to date with one hundred cases including the two of his own and my first two

I feel that although the history is most characteristic many of these cases are not detected, due largely to the fact that few surgeons think of this as one of the causes of urinary incontinence. A general appreciation of the fact that with such a characteristic history, this is about the only condition to produce it, would, I am sure bring to light many of these anomalies

A brief account of the embryological development of the ureter will be helpful to illustrate and understand how this anomalous condition arises. The best account I have found in English is that of Kelly and Burnham, briefly stated it is

The ureter arises as a process from the hind wall of the lower end of the Wolffian duct. The distal end of this bud grows into the kidney and, as the kidney ascends into the lumbar region, the ureter lengthens—at first the ureter opens into the Wolffian duct, but later it opens with the Wolffian duct into the urogenital sinus. Should the Wolffian duct or the ureter fail to shift anterior from the cloaca before the urorectal septum divides the rectum and the bladder, the ureter empties into the rectum. In the female, should there be a failure of separation of the Wolffian duct and the ureter, the ureter will be connected with Gartner's ducts and the structures developing from the Wolffian duct, namely, the urethra, and the vestibule of the vagina

Of the several theories advanced to explain the double ureter, the most plausible is that there

are two separate evaginations from the Wolffian duct. In the process of down growth the lower ureter reaches the bladder first, usually in the place where the normal ureter is found, while the upper ureter continues its downward shifting together with the Wolffian duct, mesially to the first attached ureter until it reaches the urogenital sinus. The Wolffian duct minus the ureter continues to shift to a still lower level. If the two ureters are liberated in quick succession they will be found close together in the bladder; if a long interval prevails they are further apart so that the upper ureter may be carried even to or below the internal urethral orifice

The practical points learned from this embryological study are

- 1 A double ureter may unite at any point between the bladder and kidney and empty into the bladder as a single tube.

- 2 When there are two separate openings into the bladder there are two complete ureters

- 3 The ureter opening most caudad comes from the cephalad portion of the kidney and that from the lower pole occupies the more normal position in the bladder

- 4 The ureteral opening, when in the urethra, is always on the floor and never on the roof or lateral walls

- 5 When the ureteral opening is in the vagina it is on the anterior wall and never on the lateral wall

- 6 The ureter emptying lowermost crosses and lies to the inner side and behind the more normally situated ureter

- 7 In the female the ureter may empty into the vagina, the vestibule of the vagina, the fallopian tubes or uterus, or Gartner's duct. In a number of non-viable fetuses openings into the rectum, intestines, and allantoic cavities have been discovered. In the reported cases the openings have been

First, in the urethra. In two of these the opening was through the sphincter and there was fairly good urinary control. In one of these two the incontinence did not appear until after the

## THE RAPID GROWTH OF INTRAVENOUS MEDICATION

It is very evident that intravenous injection is being rapidly adapted as a regular office and bedside technic by the general practitioner Some years ago we heard a great deal of opposition to it, although the logic of the method could hardly be disputed This, however, is being overcome.

The opposition, to a great extent, was the result of early attempts with large volume of extemporaneous solution Much of it was mere prejudice

Loeser has studied some thirty odd U S P and standard remedies of established therapeutic value as to their adaptability for intravenous injection Each drug required individual study The action of these remedies on the blood was first ascertained by animal injections Then by clinical trials proper dilution and dosage were ascertained Loeser has demonstrated that in order to make the technic safe and practical 5cc. to 20cc of solution should be injected instead of large volume

that often the orifice of the ureter may be stric-  
tured, and the ureter and its pelvis dilated. When  
in the erect position the hydrostatic pressure is  
sufficient to cause a relatively rapid emptying of  
the ureter and pelvis, which will later be gradu-  
ally refilled. During the filling time the patient  
may be dry. The amount of the abnormal drain-  
age is dependent also upon the amount and the  
function of the renal tissue connected with the  
anomalous ureter. Two of the reported cases  
with the ureters emptying into the urethra  
through the sphincter were not troubled until  
after labor, which evidently caused a sphincter  
weakness, that allowed the urine to flow from  
urethra rather than back into the bladder.

Such a history as just related is so character-  
istic that one should cling to the idea of an ex-  
travesical ureteral opening until it is located or  
some other cause found to account for the incon-  
tinence.

*Examination*—Inspection of the vulva, vag-  
ina, and urethra may locate the opening if the  
amount of leakage is great. Such simple inspec-  
tion is rarely successful. The better method is  
to give the patient indigo-carmine or phenol sul-  
phonephthalein, intravenously, to stain the urine.  
If the function of the kidney drained by the aber-  
rant ureter is deficient, or if there is marked  
hydro-nephrosis, or hydro-ureter, sufficient dye  
will not be excreted to show. When dye is  
excreted, but the opening cannot be found, the  
vestibule, vagina, and urethra should be tamponed  
for a few minutes. The stained spot will be a  
pointer to the opening.

Failing in the above, radiographs of the kidney,  
if sufficiently clear, may show some distortion, or  
irregularity, that would indicate the side from  
which the aberrant ureter comes. An indirect  
way of determining this when the amount of  
kidney substance attached to the involved ureter  
is sufficient, is to make a pyelogram, by injection  
through the ureter that opens into the bladder.  
The absence of the upper calyces would be most  
suggestive. In my third case this was of no help  
as the normally situated ureter drained a practi-  
cally normal kidney and gave a normal pyelo-  
gram. In one of his patients, Killian was able  
to show the pelvic deficiency very well.

A few instances are reported of finding the  
ureteric opening in the urethra by endoscopy.  
This is most difficult, and a fortunate outcome  
of such an examination is largely a matter of  
luck.

A method of differentiating bladder and ure-  
teral leakage is to fill the bladder with indigo-  
carmine solution, and then inject phenol-ulpho-  
nephthalein intravenously. If the leakage is  
from the bladder the staining will be blue. If  
from an extra-vesical ureter the color of the  
phthalein-yellowish in acid urine, red in alkaline,  
providing there is a sufficient amount of function-  
ating kidney. (The phthalein excreted into the

bladder will be overshadowed by the darker in-  
digo-carmine.)

Should all of these methods fail, I would con-  
sider an exploratory operation advisable. This  
may be either of the kidney, or kidneys, or  
abdomen.

If the leakage is small, and function poor, it  
would indicate that the aberrant ureter drained  
only a small amount of kidney tissue. In such  
instances the renal exploration is preferable to  
the abdominal, for in it resection is usually  
possible. A history of pain in one lumbar region  
would point to the corresponding side as the one  
probably involved. It must be remembered that  
in twenty-five per cent of the cases reported both  
sides have been involved. Without any localized  
signs or symptoms, it is an even chance as to  
the side on which the trouble will be located.  
Should the first incision fail to discover it, ex-  
ploration on the other side is warranted. The  
fact that 25 per cent of the cases are bilaterally  
involved, would not justify the exploration of  
the second side after finding and treating the con-  
dition on the first.

With the secretion from the normal kidney  
large, the function good, no pus in the urine  
that is collected by having the patient sit over  
a vessel for a time, and the possibility that a  
uretero-vesical anastomosis may be accom-  
plished, then I would say that the abdominal  
exploration for diagnosis was the better pro-  
cedure, as an ureteral anastomosis could then be  
done.

It is not only necessary to make a diagnosis  
of aberrant extra-vesical ureter, but we must  
know

- 1 What amount of kidney tissue is drained
- 2 The function of same
- 3 If there is infection
- 4 If there is ureter stricture, hydro-ureter and  
hydro-nephrosis

The first may be determined indirectly by a  
pyelogram of the lower portion of the kidney  
made by injecting the normal ureter, and  
directly when the abnormal ureter can be  
catheterized, injected, and radiographed.

The function by injection of phenolsul-  
phonephthalein and collection by ureter  
catheter, or having the patient drain the ex-  
cretion into a vessel.

The presence of infection by examination of  
the collected excretion—if it cannot be col-  
lected by catheter, then the vagina must be  
thoroughly cleansed before collecting the  
specimen in a vessel.

The fourth condition, namely stricture,  
hydro-ureter and hydro-nephrosis by ureter  
catheterization, and at times by a pyelo-  
ureterogram. This is not always possible as  
the orifice of the ureter may not be discover-  
able, or possible to be catheterized.

third labor. In still another, the continence was good even though the opening was anterior to the sphincter—this case was discovered as a post-mortem finding.

Second, into the vestibule. Most of the recorded cases have had an opening in this location and it has usually been just below the external urethral meatus and slightly lateral. It has usually been described as of slit form.

Third, into the vagina. The opening in most

numerary ureter. Probably further study will show that with accessory extravescical openings the upper pole will be found quite rudimentary. This rudimentary development, however, does not always hold true in the cases of double ureters where the opening is intraviscal as shown in one operated case by Hugh Young, one operated case and one post-mortem finding seen by myself, in all of which, the kidney tissue drained by the two ureters was fairly evenly divided.

Fig 1—Illustrating the formation of a double ureter (After Kelly and Burnham)

of the cases has been below the urethra and slightly lateral.

No matter where the opening has been, in a good majority of cases the lower end of the ureter has been dilated, either as a small sac, or as a fusiform swelling. In many instances this dilatation extended to the kidney which was found to be atrophic in the part drained by the super-

In the numerous pyelographs that have been made of double ureters, the size of the pelvis would indicate the same.

*History*—The usual history is one of constant leakage from birth, in addition to normal voiding. This leakage may vary during the twenty-four hours, as influenced by exercise, posture, etc. This is easily understood when it is remembered

through normally situated right and left ureters. The vagina and the vestibule were packed with cotton. After a wait of ten minutes it was found that the cotton just below the urethral meatus was stained. A careful search revealed a minute opening, into which a ureteral catheter could be introduced four inches. Vaginal palpation showed this to run to the left side.

**Operation**—After catheterizing the ureter, an attempt was made to dissect it out, and turn it into the bladder. A thin fusiform sac intimately adherent was found. This was opened accidentally. After this an incision was made into the bladder through the opposite wall of the sac and the vesical and ureteral mucosae united with catgut. The distal end of the ureter was closed, the accidental wound sutured, and the vagina brought over it with chromic catgut. A retention catheter was placed in the bladder.

Seven days after operation the old ureteral leakage returned. After three weeks the ureter was exposed through the vagina, and it was then found to be about twice the normal thickness on the kidney side of the fusiform sac. After mobilizing  $\frac{3}{4}$  of an inch of the ureter, a sound was placed in the bladder, made to depress the bladder just in front of the ureter. A hole was cut at this point, a suture placed through the ureter and tied to the sound. On withdrawing the sound the ureter was pulled into the bladder, where it was sutured with chromic catgut and the vaginal wound closed.

The incontinence was cured. After operation the new opening was shown to function by the appearance of indigo-carmin elimination, but after six months this ceased. Attempts to catheterize this ureter were vain.

**CASE 2**—A woman of 38 with a history of incessant dribbling and normal micturition. Cystoscopy showed two normally situated ureters, both eliminating indigo-carmin promptly, but an opening of an extravasical ureter could not be found. Cotton pledgets were placed after indigo-carmin administration to detect any extravasical discharge but none was found. On vaginal examination the urethra appeared more full and prominent than usual. A metal catheter was placed in the bladder and the urethra again palpated without detecting any swelling beneath.

The patient had a fibroid uterus the size of a grape fruit, and because of three weekly profuse bleeding, I did a supra-vaginal hysterectomy. On the right side of the pelvis was found a soft elastic swelling which was extraperitoneal, about three-quarters of an inch in diameter, running from below upwards over the brim of the pelvis. The history, together

CASE 2

Fig 6 The enlarged supernumerary ureter is shown draining the small upper portion of the kidney. This portion of the kidney had its own blood supply, and was separated from the larger portion without bleeding. The supernumerary ureter was greatly dilated. The two ureters were closely attached, but were easily dissected free.

with the knowledge of two normally placed ureters, each promptly eliminating indigo-carmin, gave the clue to the diagnosis. Palpation of the right kidney showed a mass the size of a hickory nut on the superior pole.

Not trusting the efficacy of simple ligation of the ureter, an upper right rectus incision was made into the peritoneal cavity. An incision was made through the peritoneum on the outer side of the colon which, when displaced inwards, exposed the kidney. The dilated ureter was in front of the other ureter and closely connected. At the pelvic brim the dilated ureter so overlaid the other that it was not to be seen. The ureter 3 inches from the pelvis was freed, double clamped and cut. The lower end was ligated with chromic catgut and dropped. The renal end was freed up to

**Treatment**—The reported cases have been treated in various ways

1 Ligation of ureter, through vagina, just above the bladder or below the kidney

2 Uretero-vesical anastomosis, vaginal, abdominal, both intra and extraperitoneally

3 Formation of openings between ureter and bladder, by plastic operation through the vagina and after supra-pubic cystotomy Also cauterization of the dilated ureter through a cystoscope

4 Resection of the kidney

5 Nephrectomy

Ligation of the ureter has been reported as successful in five instances Personally, I doubt the advisability of it in any instance as the problems are better handled by other methods

Cases suitable for uretero-vesical anastomosis These show a goodly amount of renal tissue drained by the accessory ureter, no infection, good function, and absence of hydro-ureter and hydro-nephrosis The choice of the vaginal or abdominal route for this implantation is dependent on the condition of the lower end of the ureter Should it be easy to dissect out and not dilated, implantation per vaginam is a simpler and safer procedure than by abdomen Should this be a failure, the result is not serious and an abdominal implantation may be done at a later date I believe that the extraperitoneal operation for the abdominal implantation is a better and safer procedure than the intraperitoneal In some instances of good function but of mild hydro-ureter and hydro-nephrosis, and slight infection, suitable treatment may correct the conditions sufficiently to put them in this class

A few cases will require nephrectomy if the function of both parts of the kidney is low, or if the blood supply of the kidney makes resection of the upper pole impossible, and uretero-vesical anastomosis is undesirable

A primarily satisfactory uretero-vesical anastomosis may later prove very disappointing The ureter may become strictured, infection take place, and distention of the pelvis and ureter occur—conditions that will destroy the kidney function and possibly cause a troublesome cystitis

Hunner was able to connect the aberrant ureter to the bladder by first inserting a minute rubber bag in the ureter distending this and cauterizing the tissue between the bladder and ureter through a cystoscope In my third case such a connection could have been established by fulguration This method often has the disadvantage of draining infected fluid into the bladder, with the probable development of a chronic cystitis

#### CASE I

Fig 2. The dilated distal end of the supernumerary ureter shown as a fusiform sac, with a minute orifice below the urethra.

Fig 3 The result of the first operation—an opening between the dilated lower end of the supernumerary ureter and the bladder, and an opening between the ureter and the vagina, the result of failure of union of the vaginal wound.

Fig 4 The end result—the supernumerary ureter implanted in the bladder

Fig 5 The opening of the supernumerary ureter is shown below the ureter In life this was not so large nor so distinct. The line shows the incision made through the perineum to gain access to the base of the bladder

After a study of my own cases and those in the literature, I feel the problem narrows itself down to three methods of treatment First Uretero-vesical anastomosis if there is no infection and the amount of renal tissue that may be saved is worth while Second Resection of the kidney Most cases will fall in this class The operation is usually easy and the results most satisfactory Third An occasional case may require nephrectomy because of an anomalous blood supply that makes resection impractical, or severe functional damage to both portions of the kidney

CASE 1—A girl of nineteen who came on account of incessant dribbling since birth She voided as other normal girls This history pointed clearly to some congenital anomaly, one in which urine was discharged distal to the urethra With this in mind, she was cystoscoped after intravenous injection of indigo-carmin. The dye was eliminated promptly

through normally situated right and left ureters. The vagina and the vestibule were packed with cotton. After a wait of ten minutes it was found that the cotton just below the urethral meatus was stained. A careful search revealed a minute opening, into which a ureteral catheter could be introduced four inches. Vaginal palpation showed this to run to the left side.

*Operation*—After catheterizing the ureter, an attempt was made to dissect it out, and turn it into the bladder. A thin fusiform sac intimately adherent was found. This was opened accidentally. After this an incision was made into the bladder through the opposite wall of the sac and the vesical and ureteral mucosae united with catgut. The distal end of the ureter was closed, the accidental wound sutured, and the vagina brought over it with chromic catgut. A retention catheter was placed in the bladder.

Seven days after operation the old ureteral leakage returned. After three weeks the ureter was exposed through the vagina, and it was then found to be about twice the normal thickness on the kidney side of the fusiform sac. After mobilizing  $\frac{3}{4}$  of an inch of the ureter, a sound was placed in the bladder, made to depress the bladder just in front of the ureter. A hole was cut at this point, a suture placed through the ureter and tied to the sound. On withdrawing the sound the ureter was pulled into the bladder, where it was sutured with chromic catgut and the vaginal wound closed.

The incontinence was cured. After operation the new opening was shown to function by the appearance of indigo-carmin elimination, but after six months this ceased. Attempts to catheterize this ureter were vain.

**CASE 2**—A woman of 38 with a history of incessant dribbling and normal micturition. Cystoscopy showed two normally situated ureters, both eliminating indigo-carmin promptly, but an opening of an extravascular ureter could not be found. Cotton pledgets were placed after indigo-carmin administration to detect any extravascular discharge but none was found. On vaginal examination the urethra appeared more full and prominent than usual. A metal catheter was placed in the bladder and the urethra again palpated without detecting any swelling beneath.

The patient had a fibroid uterus the size of a grape fruit, and because of three weekly profuse bleeding, I did a supra-vaginal hysterectomy. On the right side of the pelvis was found a soft elastic swelling which was extra-peritoneal, about three-quarters of an inch in diameter, running from below upwards over the brim of the pelvis. The history, together

CASE 2

Fig 6 The enlarged supernumerary ureter is shown draining the small upper portion of the kidney. This portion of the kidney had its own blood supply, and was separated from the larger portion without bleeding. The supernumerary ureter was greatly dilated. The two ureters were closely attached, but were easily dissected free.

with the knowledge of two normally placed ureters, each promptly eliminating indigo-carmin, gave the clue to the diagnosis. Palpation of the right kidney showed a mass the size of a hickory nut on the superior pole.

Not trusting the efficacy of simple ligation of the ureter, an upper right rectus incision was made into the peritoneal cavity. An incision was made through the peritoneum on the outer side of the colon which, when displaced inwards, exposed the kidney. The dilated ureter was in front of the other ureter and closely connected. At the pelvic brim the dilated ureter so overlaid the other that it was not to be seen. The ureter 3 inches from the pelvis was freed, double clamped and cut. The lower end was ligated with chromic catgut and dropped. The renal end was freed up to

the vessels going to the lower part of the kidney and then passed above them. It normally ran posteriorly to the vessels. The kidney was normal in size with the part attached to the extra ureter perched on top. Two small arteries ran to it—the veins could not be well shown. This part of the kidney was represented by a sack  $\frac{3}{4}$  of an inch in diameter, with a small layer of kidney tissue attached to the kidney, the whole being enclosed in a fibrous capsule. It was resected without difficulty and without bleeding.

A stab wound was made in the flank, through which a cigarette drain was placed, the posterior peritoneal incision, and the abdominal wound were closed. There was only slight bloody drainage. The drain was removed on the second day. Uneventful convalescence with complete relief of urinary drainage. On two subsequent examinations the opening of the ureter could not be found.

**CASE 3**—This patient was seen first in 1915 when 16 years old. Her mother stated that she had always dribbled urine, as well as voiding normally. This leakage seemed to be greater in the morning than later in the day. As she grew older it was noticed that there was less after exercising and dancing than at other times. There would be periods of one to two hours during the day when she would be dry.

Pus in small quantities has been found in the urine at all times. On only one occasion, blood and then only a few cells. In October, 1915, she had left lumbar pain for a brief period. At this time the only positive finding was a mild trigonitis. She was requested to return for further examination, after having radiographs, but disappeared until April 10, 1925.

The condition had persisted and had been worse since a very difficult high forceps delivery July, 1924. This dribbling is not troublesome when in bed, is worse when standing, and is not influenced by sneezing or coughing.

**Examination**—Both ureters appear normal and excrete indigo-carmin equally. Just within the urethral orifice on the right was found a small cystic mass, surrounded by moderate bullous edema. An extra-vesical ureter was suspected, but could not be found. Radiographs were made which showed the left kidney enlarged and lobulated. Later a pyelogram was made after injecting the left ureter. This was done with the idea that if there were two ureters from this kidney an abnormality of the pelvis would be detected—but the pelvis appeared normal.

**Operation**, May 12, 1925—Thinking that the cystic mass noted at the vesical outlet might be a cause of the trouble, a supra-pubic cystot-

omy was done with the intention of removing it. This mass appeared in the bladder the size of a pea. In dissecting it out an incision was made into it—there followed the escape of fully three ounces of fluid. A probe could be passed its length (eight inches) up the left side towards the kidney. This corroborated my first suspicion of an aberrant ureter. The opening into the ureter was enlarged, and the mucosa of the ureter and that of the bladder united. A rubber drain was inserted into the ureter, and the bladder drained suprapubically. Both drains removed on the seventh day.

Following this operation she at times had leakage below. She was seemingly not benefited by the operation. On June 8, 1925, the left kidney was exposed. On its upper pole was a flabby mass the size of an English walnut with a ureter the size of a lead pencil running behind the ureter of the normal size kidney. There was no direct blood supply to the kidney. The supernumerary portion was easily separated from the kidney, the bleeding was slight, only one small artery needed ligating. The moderate oozing was controlled by a few mattress sutures of chromic catgut. Cigarette wound drainage for 48 hours. Uneventful convalescence.

The leakage still persists. It does not come from the bladder, as indigo-carmin solution injected into it does not escape. The leakage is a colorless fluid containing a small amount of pus and comes via the urethra. Phenolphthalein injected intravenously is not detectable in this. From a study of the facts, I feel sure that she has a poorly functioning amount of renal tissue on the right side, drained by a ureter that opens somewhere in the urethra.

In a review of the history and the operative findings, the patient's statement that the leakage is worse in the morning, and is less after exercise is understandable. A relatively large amount of urine would be collected in the dilated ureter and pelvis, that would be discharged rather rapidly when she was erect or exercising. Following this the filling would be slow because of the small amount of renal tissue.

The following is the pathological report of Case No 3, by O. S. Hillman.

**Gross Examination**—The specimen consists of a small, shrunken kidney, measuring 5.5x4.5 cm, with 5 cm of the ureter attached.

The kidney is roughly oval in contour, with blunt poles and a coarsely lobulated and somewhat fissured surface. Toward one pole on the hilus aspect, there is a cavity into which a probe can be passed up to the opposite pole. This would seem to represent a dilation of the pelvis with compression atrophy of the paren-

chyma (?) The ureter is patent throughout. At the entrance to the ureter, the pelvic tissue is heaped up, and granular in appearance; probably the result of an old inflammatory process. There is about 1.5 cm of cortex and subtending kidney tissue in the neighborhood of the uretero-pelvic junction. No stones or abscesses apparent.

*Microscopic Examination* — Sections were taken through the last mentioned thick portion of the specimen, and also through the cystic end.

The former show well-defined kidney parenchyma, with tubules, glomeruli, and blood vessels, etc. The pathological changes are of a degenerative and chronic inflammatory character as evidenced by the presence of dilated tubules, hyaline casts, tubular edema, a few sclerosed glomeruli, foci of round cell infiltra-

tion and interstitial fibrosis, especially in the cortex, where strands of connective tissue extend from the capsule inward, the latter is thickened in places. The blood vessels show sclerotic changes.

The sections through the cystic end show atrophy of the parenchyma and a more marked degree of inflammatory degeneration.

In the region of the pelvis there is apparent evidence of an old standing chronic pyelitis.

No indication of tuberculosis can be found.

*Remarks*—A consideration of the gross and microscopic findings suggests that the pyelitis originated the degenerative changes observed in the parenchyma. The probability of a direct ascending infection might be considered in this connection.

## DISEASES OF THE LIVER AND BILIARY PASSAGES—THE CLINICAL APPLICATION OF SOME RECENT INVESTIGATIONS\*

By CHARLES S. McVICAR, M.D., ROCHESTER, MINNESOTA

From the Division of Medicine, Mayo Clinic

**D**URING the last few years important facts have been added to our knowledge of the physiology of the liver and biliary passages in health and disease. It is my purpose in this paper to indicate how certain of these facts may be, and have been, applied with advantage at the bedside. References to much fundamental research must be omitted from such a review only because it is not yet possible to assess the clinical value of these studies. The interposition of the liver between the intestines and the general circulation calls immediate attention to the physiologic importance of this organ. A formidable hindrance to a study of the details of hepatic deficiency is the large reserve of the organ. A practical method of studying the function of any organ is to estimate the effect of removing part of it. Mann and Bollman have shown that it is possible to remove at one time, without any obvious effect on the animal, as much as two-thirds of the organ.

### FUNCTIONS OF THE LIVER

The functional unit of the liver is the parenchymal cell, commonly known as the polygonal cell or, better, the hepatic cell. Our present conception of a hepatic cell is that it is a complex workshop, housing many activities. Sugar is received and converted into glycogen, the glycogen is reconverted into sugar and is released into the general circulation, protein derivatives ar-

riving by the portal circulation are detoxicated, bilirubin is separated from the blood and excreted in the bile, the metabolism of fat, cholesterol and iron, or compounds of them, is probably influenced by this workshop, fibrinogen is manufactured, and the heat regulation of the body is in part dependent on the hepatic integrity. It seems probable that in health the various activities of the hepatic cell are coordinated and interdependent, each activity receiving help from, and in its turn rendering assistance to, all other activities. In disease, however, there is abundant clinical evidence that the suspension of a single activity, for example, bile formation, is not accompanied by a corresponding degree of diminution in other functions, such as the regulation of the blood-sugar level. The measurement of any single hepatic function does not, therefore, give a comprehensive, or even quantitative, idea of its functional activities. These acknowledged difficulties have not dismayed investigators, and contributions to our knowledge of the healthy and diseased liver are being made by internists, surgeons, pathologic anatomists, biochemists and physicists. Every real advance depends on a fundamental investigation and every fundamental investigation clears the way to a real advance.

### BILE

Bile pigment is probably one of the least important constituents of bile, but we are attracted to a study of it because of its color and because, in a sense, we know more about it than we do

\*Read before the Medical Society of the State of New York, New York City, March 30, 1926.

of the bile salts, cholesterol or other constituents of bile. We are interested in the rôle of bile salts at present, and Aldrich and Greene are working on a method of measuring the quantity of bile salts in the blood and other body fluids. They believe they have a method with but a small range of error and sufficiently accurate to give significant relative values.

*Source of Bile Pigment*—Our chief recent interest in bile pigment is due to the discovery by the Dutch physiologist, van den Bergh, that the very simple diazo reagent produced a characteristic color in solutions containing bile pigment, which made it possible to estimate the quantity of pigment in a solution by comparing the depth of color with standards. It is generally agreed that the source of bile pigment is the broken-down molecule of hemoglobin, that the pigment is an iron-free hematin derivative. It is further assumed that the pigment is actually manufactured by reticulo-endothelial cells, which are collected in great abundance in the spleen and bone marrow. Bile pigment is normally present in the serum of man in an appreciable amount. That it is actually manufactured in the spleen and bone marrow has been conclusively shown by Mann, Sheard, Bollman and Baldes. Sheard, as a physicist, has brought to this investigation the spectrophotometer, which enables us not only to identify bilirubin as such, but also to measure it in smaller quantities than had hitherto been possible by any colorimetric method. These investigators have taken the blood from the vessels going to the spleen and to the bone marrow, and have contrasted it with blood coming from these areas and have shown that the blood coming away has an appreciably greater content of bilirubin. Mann, Bollman and Magath had previously shown that when the liver is completely removed from the dog the animal becomes jaundiced during its period of survival, thus indicating that pigment was formed outside the liver. It may be assumed, therefore, that with regard to pigment the liver is chiefly, although not exclusively, an excretory organ. Some pigment is presumably manufactured by the reticulo-endothelial cells of the liver itself. Our chief interest in the van den Bergh reaction, from a clinical standpoint, is its variation under different physiologic and pathologic conditions. In the blood going to the liver, color can be produced, not simply by the addition of the reagent to the serum, but by the addition of something else, namely alcohol, to bring up the color. In this respect it differs from bile itself, in which the color is immediately produced on the addition of the reagent. This suggests that the pigment molecule in its progress through the parenchymal cell of the liver is altered, perhaps it loses something, presumably protein. Now if this molecule is reabsorbed into the blood after

it has passed through a hepatic cell, it then gives a direct reaction, that is, the color comes up at once on the addition of the reagent to the blood serum and without the necessity of adding alcohol. We have, therefore, means of telling whether the pigment in the circulating blood represents reabsorbed pigment or what may be termed bile pigment proper.

*Pathologic significance of bilirubinemia*—Excessive pigment in the circulating serum can occur for either of two reasons. First, pigment may be produced in excess in the spleen and bone marrow so that it may exceed the ability of the liver to remove it from the circulation. In this case, the quantity is increased but the reaction is indirect. On the other hand, it may be due to obstruction in the extrahepatic biliary passages, which causes bile to dam back and bile pigment to overflow into the capillary bed of the liver and be reabsorbed into the general circulation. The van den Bergh test may assist in differentiating between hemolytic and obstructive jaundice. When an excessive quantity of pigment is produced an indirect reaction is found, thus supports other clinical evidence of hemolytic icterus, especially splenomegaly, increased fragility of erythrocytes, and the absence of pruritus. In cases of obstructive jaundice the test is of very definite value because it enables us to distinguish mild grades of obstruction. This is because the plasma may show an excess of pigment giving a direct reaction without there being enough pigment to produce any yellow tint in the sclerotics or skin. It is also a fact that an increased quantity of pigment is discernible in the plasma for an appreciable time before it appears in the sclerotics or other tissues, and conversely, the pigment content of the plasma returns to normal appreciably sooner than the color will disappear from the sclerotics or other tissues. In actual practice, the van den Bergh method of measuring the quantity of pigment in the circulating blood is much more precise than any known method of contrasting variations in the tint of the skin or sclerotics from day to day. The surgeon is thus able, when contemplating operation, to estimate from day to day the quantity of pigment due to obstruction and to avoid operation in the presence of that rising curve of bile in the blood that presages postoperative hemorrhage. In event of a falling curve he will delay operation because the risk of hemorrhage declines with the curve, and he is able to select the optimal time for operation in each individual case.

The van den Bergh test enables one not only to estimate the circulating pigment quantitatively but to distinguish qualitative differences, in this respect it is superior to the icteric index. Occasionally, a yellow color is imparted to the plasma by vegetable pigments, especially carotin

These pigments interfere with accurate estimation of the icteric index, but do not interfere with the van den Bergh readings

An interesting and practical application of the van den Bergh test has been made in the study of a few cases of pruritus. Dermatologists have for a long time suspected metabolic disorders as a cause of certain cases of pruritus. French investigators<sup>3</sup>, especially, have written in support of the theory of dissociated jaundice. This conception of dissociated jaundice presupposes a selective difference in the retention of bile constituents in the tissues, thus bile salts may be retained while pigment is excreted, and to the retained bile salts have been accorded the property of inducing pruritus, bradycardia, decreased coagulation of the blood, and so forth. Stimulated by this hypothesis, we have studied a few cases of persistent and troublesome pruritus without jaundice and have found that in certain of them the plasma showed a normal quantity of bile pigment but that the pigment present gave a direct reaction. In these cases also the liver shows decreased ability to excrete phenoltetrachlorophthalein. We have not been able positively to ascribe the itching to an excess of bile salts, but the finding of a direct van den Bergh reaction with a normal quantity of bilirubin, supported by dye retention, associates the pruritus definitely with a disturbance of hepatic function.

#### TEST OF HEPATIC FUNCTION BY DYES

Several years ago Abel and Rowntree, while studying the pharmacologic action of phenolphthalein, showed that this substance was excreted in the urine and in the stools. This led to experimenting with variations in the phenolphthalein molecule, which resulted in the discovery that the substance phenolsulphonophthalein was excreted quantitatively by the kidneys, and that the substance phenoltetrachlorophthalein was excreted quantitatively in bile. These dyes consequently were used by Rowntree as tests of renal and hepatic functions, respectively.<sup>13, 14</sup> More recently, Graham and his coworkers have substituted for the chlorine radical, other halogens, iodine and bromine, and have found that these combinations render the bile opaque to the roentgen ray.

Use is made of the fact that phenoltetrachlorophthalein is excreted quantitatively in the bile to estimate the function of the liver. The method of its use has been simplified by Rosenthal. The procedure is to inject a measured amount of this innocuous dye (bromsulphthalein) into the vein of one arm, to remove samples of blood from the other arm at intervals of fifteen and sixty minutes, and to see how much dye remains in the general circulation. If the liver maintains its ability to excrete dye, it disappears very rapidly from the blood. If this function

is interfered with, there is a retention of dye in the blood. The method is especially useful when there is no obstructive jaundice. In obstructive jaundice there is, of course, interference with the flow of bile and, consequently, interference with the flow of dye.

#### CHOLECYSTOGRAPHY

The present method of cholecystography is founded on this selective excretion by the liver of compounds of phenolphthalein. The factors which enter into the interpretation of the results of cholecystography are indicated in Figure 1.

The diagram illustrates the course of the opaque phthalein compound when administered orally, in which case it reaches the liver by way of the portal circulation. If the drug is administered intravenously it reaches the liver by way of the general circulation, that is, through the hepatic artery. The intravenous method is theoretically preferable since absorption is assured. In my experience intravenous injections of available preparations have not been free from the objection that painful local phlebitis may be set up at the point of injection, and that a severe constitutional reaction may occasionally alarm the patient.

Refinements in the use of the method may be expected to follow experiments to produce the greatest concentration of the substance in the bile, and the careful collection of data with respect to the two important facts: (1) whether a diseased gallbladder may sometimes fill with the opaque bile, and (2) whether a gallbladder which fails to fill is always seriously enough diseased to warrant its surgical removal.

Undoubtedly, the most important limitation to its clinical use is the fact that in obstructive jaundice, the opaque dye is not excreted. The method at present, therefore, can give us no reliable information with respect to the condition of the gallbladder when jaundice is present.

Carman has recently summarized our experience of cholecystography in approximately 2,000 patients, of whom 737 were operated on. He estimated the percentage of error in diagnosis by this means as 23.6 per cent. This report is, I believe, very conservative. In approximately two-thirds of the 174 errors the excised gallbladder showed a mild degree of disease. Previous to the use of opaque dyes in roentgenologic studies of the gallbladder, negative findings had very little value. The present method has increased the value of negative findings from less than 20 per cent to more than 75 per cent.

#### EXPERIMENTAL HEPATECTOMY

Mann and his coworkers have been able, by a special technic, to remove the liver completely from a dog and have the animal survive for

FIG 1 FACTORS IN CHOLECYSTOGRAPHY (ORAL METHOD)

## FACTORS IN CHOLECYSTOGRAPHY (Oral Method)

- 6 Interpretation
  - (a) Does a diseased gallbladder sometimes fill
  - (b) Does failure to fill indicate a degree of disease which warrants surgical removal

several hours after this procedure. A striking effect of the removal of the liver is the progressive decline in the sugar content of the circulating blood. The period of survival has been increased by the intravenous use of glucose solutions. This gives us a practical hint in the management of cases in which gross disease of the liver and gross interference with function are suspected. If we wish to protect the organism against dysfunction of the liver, we can with advantage make use of a high sugar content in the diet and use glucose solutions intravenously. Mann's experiments also show that when the liver is removed, the formation of urea from the waste products of nitrogen metabolism ceases. These waste products are toxic and are normally converted into the nontoxic urea for excretion in the urine. It is, therefore, fair to assume that when the liver is seriously damaged, the organism is less able to metabolize protein, which should be excluded from, or limited in, the diet. It should perhaps be mentioned that Mann's dehepatized dogs finally die in a state of shock, which is probably not a hypoglycemic state, in clinical practice in the most advanced cases of injury or damage to the liver, it is rare to find the blood sugar depleted.

## ANATOMIC STUDIES

McIndoe and Counseller have injected the biliary and vascular systems of livers removed at necropsy, and have then corroded the remaining hepatic tissue so as to reveal graphically the variations from normal which disease produces in these systems. In obstructive jaundice of

short duration, the dilatation of the intrahepatic bile passages is enormous, producing in fact a hydrohepatosis analogous to hydronephrosis resulting from obstruction of the urinary passages. This phenomenon indicates the necessity for early relief of obstruction. They have further shown that when obstruction due to stone in the common duct or traumatic stricture persists for longer than about three weeks, extreme fibrosis of the biliary passages occurs, leading to permanent dysfunction of the liver and pointing again to the necessity of early relief of obstructive jaundice. They have been able to demonstrate graphically a tremendous diminution in the vascular system in the presence of cirrhosis.

## ASCITES

One of the most distressing clinical effects of cirrhosis is the accumulation of ascitic fluid in the abdomen. The operative removal of ascitic fluid is seldom perfectly satisfactory. It is accompanied by danger of infection and is annoying to the patient. The establishment of collateral circulation by surgical means in the attempt to assist nature in the removal of the ascitic fluid is also unsatisfactory. It is encouraging, therefore, to have at our disposal other therapeutic means of getting rid of ascitic accumulations. Rowntree, Keith and Barrier recently reported the results of the use of novasurol in the treatment of ascites due to hepatic disease in a series of twenty cases. Merbaphen (novasurol) is a drug introduced by Zieler in 1917 for the treatment of syphilis, and contains

33.9 per cent mercury Keith believes that diuresis from the use of the drug is enhanced by the simultaneous administration of ammonium chlorid or nitrate and by a low intake of salt in the food (6)

#### TREATMENT OF HEPATIC DYSFUNCTION

Walters has previously reported the lowering of the operative mortality which has resulted at the Mayo Clinic from the routine use of calcium chlorid intravenously in the preparation of jaundiced patients. The details of our preparation of patients with hepatic dysfunction may be summarized as follows

To prevent postoperative hemorrhage (1) calcium chloride intravenously, 5 cc of a 10 per cent solution daily for three days, (2) a study of blood coagulation (method of Lee and White), (3) transfusion of blood if prolonged coagulation time persists

To anticipate failure of hepatic function (1) high carbohydrate content of food, (2) glucose solutions, proctodysis, 2 per cent, 1,500 c.c. daily, intravenous injection, 10 per cent in marked prostration and dehydration.

To fill up tissue reservoirs, to ensure adequate renal function, and to compensate for possible loss of fluid following necessary drainage of bile the use of from 3 to 4 liters of fluid daily

The methods of study here outlined are additions to, and not substitutes for, the subjective history, physical examination and routine observation of urine and stools. Each study reviewed has, however, contributed something of value in the diagnosis and management of diseases of the liver and biliary passages

## THE AGE OF PUBLIC HEALTH\*

By MATTHIAS NICOLL, JR., M D, ALBANY, N Y

Commissioner of Health, New York State.

I HAVE chosen as a text for the somewhat discursive observations which follow a remark once made to me by Dr Herman M Biggs to the effect that sound public health work always progresses. Dr Biggs did not mean by that statement that there were no periods in the progress in which the work seemed to pause or even lose ground, but that the tendency of a line representing results accomplished, even though broken here and there, is always upward.

Apart from mechanical inventions, discoveries in the field of physics and their application to the satisfaction of human needs, nothing is more characteristic of the age in which we are living than the widespread interest in public health, and the recognition of its vital importance to the present and future welfare of the human race.

The story of the beginning of modern public health, its astonishing growth and development, and the triumphs that have followed in its wake have been so frequently set forth and are so generally known to you that I need not recount them at this time, beyond calling attention to a few striking or rather dramatic accomplishments in this field. Through the work of the great foundations, notably the International Health Board, co-operating with and aided by advice and financial support from local and federal health agencies, we have seen within the last comparatively few years vast regions of the earth, widely separated, freed from the ravages of the endemic diseases which formerly made them almost unfit for human habitation—much less for human progress—incalculable numbers of lives saved, commerce and industry introduced or restored, and a sense of security and contentment replacing dread, torpor and despair. In our own country, notably in some parts of the South, dysentery, typhoid fever, malaria and hook worm are rapidly yielding to the sound application of the principles of preventive medicine. Here, too, thousands of lives are being saved and equally, if not more important, those afflicted with parasitic disease, and thereby reduced to a mental and physical condition which made them human beings in name only, have been restored to a life of hope and usefulness, and their children and those that are still to be born relieved of the curse that afflicted their forebears.

Sensational results quite regularly follow intelligent and well organized public health work in virgin fields which cannot be looked for in areas in which the fundamental principles of public health have been carried on, however imperfectly, for many years. It is far more difficult to arouse

the enthusiasm and active cooperation of a population otherwise intelligent from which the ever present dread of illness and death has long since been removed or mitigated. One has only to instance the case of smallpox and compare the present difficulty of inducing people to receive immunization against it, except when it is actually present among them, with the situation of bygone days, when smallpox was a world scourge, and it was hardly possible to provide immunization for the multitude that begged for it. Today this false sense of security, in the face of warnings from health authorities, has rendered this country, as a whole, the most poorly vaccinated of any civilized nation on earth, with the possible exception of Mexico, from which reports are difficult to obtain, and whence from time to time smallpox of the most virulent type invades our bordering states and is followed by death and disfigurement among the largely unprotected inhabitants. Again, it is usually far easier to produce noteworthy results in the control of endemic disease when it involves measures which have to do with environmental conditions,—drainage, water supply and disposal of excreta,—than when it involves the inconvenience and even dread, however unfounded, which accompanies the conferring of individual immunity, and, furthermore, it is far less difficult to induce the first thousand of a population to cooperate in a public health movement than the last stubborn or indifferent hundred. That fact, it seems to me, must be constantly borne in mind. As an example although we have every reason to be happy and proud of the results already attained in the campaign against diphtheria, which has reduced illness and death from that disease to the lowest point in the history of the State, the final goal of the journey to eradicate diphtheria will prove much the hardest to travel, challenge our persistence, and call for ever increasing effort.

Occasional local outbreaks of typhoid fever may be expected even in those states in which it has become but a small factor in morbidity just so long as carriers exist who may contaminate articles of food and drink, but waterborne outbreaks of typhoid fever are a grave reflection on local public health administration, the intelligence and civic obligations of the community. Nothing is more essential to the physical needs of a people than a pure and safe water supply, and it is astonishing how much difficulty is encountered by public health officials in bringing communities to a realization of that fact, and in persuading them to expend the necessary funds for the purpose rather than on public work of far

\* Read before the annual conference of the State Committee on Tuberculosis and Public Health of the State Charities and Association in New York, January 19, 1927.

less importance to their welfare. When a satisfactory water supply has once been installed, it must be safeguarded so far as is humanly possible at all hours of the day and night, but it too frequently happens that those who are entrusted with that responsibility are chosen from false motives of economy or for political expediency rather than on account of technical and personal qualifications.

No achievement in public health is more frequently alluded to than the phenomenal decrease in deaths from tuberculosis which has taken place, especially in this country, within the last two decades. Truly this is just cause for rejoicing, but we in public health work must not claim undue credit for ourselves, for we have had as allies in the work national prosperity, gainful employment under more sanitary conditions, good food, better housing, shorter working hours, and opportunities for outdoor recreation which, to my mind, have been quite as much responsible for the results as have the efforts of public health workers. As a matter of fact, from the standpoint of public health alone, control of tuberculosis is, with notable exceptions and over limited areas of the State and country, far from satisfactory. The reporting of known cases is sadly neglected, the machinery for discovering new cases and placing them under adequate care and treatment in the incipient stage of the disease largely fails to function, provision for the care of the young who have been exposed to family infection and may themselves be infected or by reason of undernourishment likely to contract infection has made but little progress, while tuberculosis sanatoria are frequently inadequately equipped in medical and nursing personnel to render the service for which they were intended, and, finally, provision for the home supervision of the tuberculous, except in the great centers of population, is largely unprovided for. This subject will be fully discussed during the session, and the work of tuberculosis control in Cattaraugus County, the thoroughness and effectiveness of which, I believe, are not excelled and seldom equaled elsewhere in the country, will be particularly emphasized. I venture to hope that the expert knowledge of those taking part will lead to some nationwide movement for the better control of an ever-present disease which continues to sap the social and economic life of the nation.

If I have dealt almost exclusively with the control of infectious disease, it is due to my belief that this is now, and will be for many years to come, the major task of public health officials, and until such time as the machinery for performing it has reached a degree of perfection far greater than at present, we shall be wise to devote most of our thought and resources to that end rather than, leaving the work half done, venture upon new fields, however attractive and promising, which far less directly concern the public

health. We have made a brilliant start in the work of disease control. Scientific knowledge plus wise administrations of its principles and the application of each new discovery have already gone far in the saving of lives and promotion of health, and yet we have only to recall our utter inability to exercise any real influence on the spread of respiratory diseases and their complications, poliomyelitis, and the slowly but surely increasing prevalence of encephalitis with their annual mighty toll of lives, invalidism, and crippling, in order to realize that this plainly marked field of public health work may well call forth every effort of which we are capable.

The phenomenal increase in the expectancy of life throughout the civilized world is a well deserved reward for the adoption and application of the modern principles of sanitation and hygiene, but the prolongation of life per se is not an end to which we should devote our major efforts, even though to every human being it seems the most important matter in the world. Rules of life, which if followed hold out to the devotee of longevity promise of one hundred years or more of existence, are being more and more widely circulated even by otherwise sane health publicists. They unquestionably make a popular appeal. Although I have never had the opportunity to meet a centenarian, a study of their biographies, which are very apt to be published in the daily press, together with their pictures, fails to convince me either of their attractiveness or utility. However eminent their historic prototype, the lot of modern Methuselahs is far from enviable. They are of real interest only to biologists, statisticians, life insurance companies and the village in which they usually first saw the light, the despair of undertakers and annoyance to their relatives and friends, and not infrequently have attained their conquest of the years in spite of breaking all the rules of health and hygiene. Our efforts, then, should be directed not to the prolongation of life as an end to be sought, but to the prolongation of usefulness while life lasts, whether it be for fifty or one hundred years. We are too apt to measure results of public health work in terms of births and deaths, and to give too little thought to the general physical condition of a population and the prevalence in communities of acute and chronic disease and their inevitable effect on social and economic life. Morbidity statistics are today almost non-existent, extremely sketchy or unreliable. In an attempt to dispel, in a small way, this ignorance of a subject of basic public health importance, the State Department of Health, through the Division of Vital Statistics and in cooperation with several hundred practicing physicians widely scattered throughout the rural districts of the State, has begun a study of morbidity in such districts. This involves the sending, by physicians, of weekly reports of the various conditions

for which medical advice has been sought. The returns thus far give very valuable information, and the promise of obtaining, at no distant date, morbidity data which should serve as a guide to our efforts in raising the standards of health. Should this plan prove its ultimate value, I propose to carry it out on a more extensive scale and in the larger centers of population.

One of the outstanding characteristics of the American people is the vicious habit of enacting mandatory laws on every conceivable subject, a tendency which a not too friendly critic of our country pointed out not some years ago in ascribing to the American "A cynic devil in his blood that bids him make the law he flouts." In a recent article on the "Plague of Laws" published in the *American Mercury*, the author estimates that there are not fewer than ten million laws and ordinances theoretically operative in the United States today. I cannot vouch for the accuracy of his conclusion, but I am certain that you will agree that there are, on the statute books of this country, far too many "Thou shalt nots" and a minimum of "You shoulds" for the sake of your own health and happiness and that of others. As an example, while I fully realize that laws regarding prostitution serve to restrain the disorderly and vicious, and protect the innocent, all of them together have, in my opinion, accomplished far less in the reduction of the incidence of venereal disease and the treatment of the afflicted than has the force of public health education, public health clinics and demonstrations, and this is equally true regarding other matters which pertain to personal habits, human frailties and physical and mental health. Persuasion is a slow process. Its results are seldom spectacular but they are certain and durable, accomplishing far more among average human beings than attempts at legal compulsion. Those who are in a position to influence public health legislation should do everything in their power to prevent the cluttering up of public health laws with un-

necessary mandatory provisions. As a very general rule, it is far better to confer permissive powers on administrative officials to be used in their discretion than to enact compulsory statutes of wide application which it is anybody's or nobody's duty to enforce.

All of the modern discoveries of medical science would be of little avail if they were not put into application by the process of public health education, and it is unfortunate that the number of effective public health educators is so painfully small. Their noteworthy messages, when broadcast, reach the ears of a listening public as a clear note of music emerging from a very bedlam of shrieking static.

Public health education is being carried on in this country to an extent not equaled anywhere on earth, and on the whole with good results. But hand in hand with legitimate, useful and convincing public health education goes an ever-increasing host of unqualified educators, those who march in the public health parade solely for commercial reasons, promulgators of "half baked" truths or downright lies, and enemies of the public health. This state of affairs is perhaps inevitable, and the only means apparently available to remedy it is to see to it that all our methods of public health education are dignified, attractive, basically sound, free from speculative theories, and that they reach those people who are most likely to be interested in them, and who will in turn spread the message of public health to others.

Finally, I must plead guilty to having chosen a text to which, following the example of many preachers, my subsequent remarks are but remotely related. Let me repeat it, placing the emphasis where it belongs: "Sound public health work always progresses." If you believe, as I do, that this is true, you will strive, as I shall, to guide our future efforts in behalf of the public health through channels that are well charted.

## RADIUM THERAPY IN CARCINOMA OF THE CERVIX\*

By WILLIAM P. HEALY, M.D., NEW YORK, N. Y.

THROUGHOUT Europe and America, since 1915, very earnest efforts have been made by competent observers to determine whether the admittedly unsatisfactory results of treatment of carcinoma of the cervix by hysterectomy alone could be improved by the use of radium or X-ray, singly or together, or one or both types of radiation in combination with operation.

The difficulties encountered by the surgeon in

his efforts to successfully cope with carcinoma of the cervix were those common to carcinoma in any region of the body, namely, (1) lack of early diagnosis of the disease, and (2) inability to adequately and safely remove surgically the entire lymphatic drainage area through which metastases from the primary focus were sure to be disseminated.

Much effort has been made by publicity and educational campaigns to bring about earlier diagnosis in cancer of the cervix by impressing upon all women of adult age the necessity for

\* Read at the Annual Meeting of the Medical Society of the State of New York at New York, March 31, 1926.

prompt investigation by their physicians of such abnormal symptoms as vaginal discharge and bleeding from the genital tract between menstrual periods or after the menopause

It needs no argument, I am sure, for all of us to realize when either of these symptoms occurs as a result of cancer of the cervix, that only under the most fortuitous circumstance can we hope to find a lesion favorable for complete surgical removal. Leukorrhea, dependent upon cancer of the cervix, becomes evident only when the disease has assumed considerable magnitude and represents local tissue reaction to the irritation of the invading disease.

Abnormal bleeding, even in small amounts, can occur only when the integrity of the tissues has been injured or when the supporting perivascular structures have been weakened through replacement of strong connective tissues by soft, cellular cancer masses.

Hemorrhage, which is the most significant symptom from the patient's standpoint, it is therefore evident, will rarely occur without necrosis and destruction of normal tissues to some degree, and a coincident exposure to lymphatic contamination and thereby early metastases.

In the years when hysterectomy was our only resource, a careful study of the parametrial lymph glands removed with the uterus and adnexæ revealed metastases in 35 per cent to 65 per cent of the so-called favorable cases. This, I think, fairly represents the handicap under which we, as surgeons, labor when we attempt to treat early carcinoma of the cervix by hysterectomy. Bear in mind these figures indicate that one or two out of every three clinically early cases are not really early, for metastases have already occurred beyond the confines of the uterus before the disease is recognized.

At this point it seems desirable that we should know what percentage of all cases applying for treatment are clinically, i.e., surgically "early" when first seen. In the eight years from January 1, 1918, to December 31, 1925, 836 cases of primary carcinoma of the cervix were admitted to the Memorial Hospital for treatment, and of this number 101 cases, or only 12 per cent were placed in the "early" group\*.

However, according to the studies referred to above, 35 per cent to 65 per cent of these so-called favorable cases had already developed metastatic lesions in the parametrial tissues in all probability. So that it is a fair presumption that one or two out of every three cases in this group, if subjected to hysterectomy would show a recurrence of the disease within one or two years after operation.

\* Up to October 1, 1921 these cases were under the supervision of Dr. Harold C. Bailey who resigned at that time and courteously turned his records over to us.

Of the 836 cases, there were 130 cases or 15½ per cent that were grouped as borderline cases, by which we mean moderately advanced, the disease already involving the vaginal fornices or the parametrial tissues close to the cervix. In this group it may still be possible to remove the gross disease by operation, but there would be prompt recurrence of cancer in or about the vaginal vault and broad ligaments.

Hysterectomy in the borderline cases could, therefore, be only regarded as a palliative measure directed toward checking the foul discharge and the bleeding. For the remaining 72½ per cent of cases, the surgeon has little or nothing of value to offer except cauterization with the actual cautery, application of acetone, or ligation of blood vessels, or a combination of these methods.

There is then little wonder that gynecologists turned hopefully to the possibilities for valuable aid in the therapy of cervical cancer that seemed to lie in the application of radium and the roentgen ray. Today, we realize that sufficient clinical and scientific data are available from recognized clinics throughout the world, in which a careful and impartial study has been made of these therapeutic agents in the treatment of cancer, to indicate that radium and X-ray offer more than any other form of therapy in the treatment of cervical carcinoma.

So strong has the conviction become of the futility of hysterectomy in this disease that in some of the outstanding gynecologic clinics in Chicago, Philadelphia, and New York, it has been entirely discarded and treatment by radium and X-ray substituted. This, I think is one of the strongest arguments against operation, for these men are specialists in pelvic surgery and if they are willing to accept radium therapy, there is very little excuse for general surgeons continuing to treat carcinoma of the cervix by hysterectomy. It would be just as reasonable for them to treat mammary cancer by simple mastectomy, ignoring the axillary lymphatics, or carcinoma of the lip or tongue by excision of the primary lesion and neglect of the cervical lymphatics.

One does not dispute that some cases of carcinoma of the cervix have remained well after hysterectomy alone and some after cautery amputation of the cervix, but these cases are so limited in number that they only point the exception to the rule. However, personally I have no criticism of the surgeon who does hysterectomy for cancer of the cervix, limited to the portio vaginalis without any gross hypertrophy or broadening of the cervix, and of course, no evidence of parametrial involvement, providing he will promptly have the pelvic field given thorough post-operative irradiation with radium applied from the vaginal side and X-ray from the outside.

I say this because in my opinion, based upon a

very unusual opportunity to observe the clinical course of this disease in the patients under treatment at the Memorial Hospital, our problem is not how we shall treat the primary lesion in the early or favorable cases, but how shall we postpone or prevent the almost inevitable recurrence in the parametrium or the lower vagina

Considering only the very early cases, we may dispose of the primary lesion by electrocoagulation, cautery amputation of the cervix, hysterectomy or radium. With any one of these methods the primary lesion may be so thoroughly removed that there will be no local recurrence. Nevertheless, the patient will almost inevitably develop cancer in the parametrium unless further treatment is promptly instituted

To my mind there is no form of therapy today that can compare in value with radium and X-ray in delaying or possibly even preventing the appearance of cancer in the parametrium after the primary lesion has been destroyed in any one of the ways mentioned. Our studies on this point at the Memorial Hospital, we believe are sufficiently convincing to encourage a resort to thorough cross fire irradiation of the entire lymphatic drainage area as soon as possible after the primary lesion has been destroyed

Personally, I believe the entire treatment in the "early" group can be carried out by radiation therapy alone to great advantage for the patient and without resorting to hysterectomy if one has access to proper radium and X-ray facilities

When we turn to a consideration of the borderline and advanced groups, we have an entirely different problem. Here we can say without fear of contradiction that irradiation therapy represents the best and safest treatment from the standpoint of relief of symptoms, prolongation of life and, in some cases, possibly entire elimination of all active disease

Our success in the treatment of these cases will depend upon our facilities for the application of radium in an exact and scientific manner at the primary site of the disease as regards dosage, filtration, types of applicator, etc., and the coincident use of X-ray therapy for the deeper portions of the pelvis

Each patient must be individualized and treated as a separate and distinct case presenting differences in local extent of disease and in constitutional resistance. The total hours dosage of radium used will, therefore, vary according to these factors, as well as the filtration or type of applicator used, and whether or not one is planning to entirely eradicate the lesion or merely to palliate symptoms

Such phrases as therapeutic dose, physiologic dose, trial dose, test dose, etc., as used by some writers in referring to the first dose of radium applied to the cervix are, in our opinion misleading, if not harmful and should be discarded

A proper conception of the gravity of the disease and the urgent necessity for promptly checking it would indicate that the heaviest dose compatible with the integrity of the adjoining normal structures should be used for the first application in order to promptly induce the greatest possible regression at once. This also induces tissue reactions in the adjoining normal structures which we believe are advantageous in limiting the activity of cancer cells

Subsequent applications of radium will depend entirely upon the effectiveness of the first dose and the manner in which it was applied

Previous to October 1, 1921, the gynecologic service was in charge of Dr H C Bailey and the patients were treated with radium only at that time. After January 1, 1918, on the principle of cross firing the lesion and the parametrial structures, radium was applied against the vaginal vault, within the cervical canal and externally about the pelvis

Twelve per cent of all the cases treated in 1918 are still alive and it is interesting to note that five of those cases were in the advanced group. They have nevertheless lived a full seven years since treatment

From January 1, 1922, to date, I have endeavored to adhere to the cross fire method of irradiation, using the maximum primary dose of radium in and adjoining the lesion and supplementing this later with low voltage X-ray externally. Three years have elapsed for all cases treated in 1922 by this plan. There were sixteen early cases of which 68.7 per cent are still alive and well, there were 27 borderline cases of which 37 per cent are alive, 80 advanced cases of which 17½ per cent are alive

There were 29 recurrent cases accepted for treatment in 1922 after having been operated on unsuccessfully in other hospitals, and when they applied to us for treatment, definite palpable masses could be identified in the pelvis and in some instances biopsy to confirm the diagnosis was possible. Of these 29 recurrent cases, it is interesting to note that 31 per cent are still alive. These cases were all treated with radium and X-ray

Taking all cases treated on this plan from January 1, 1922 to date, we have the following results

66 early cases	81.8 per cent alive
68 borderline cases	66 per cent alive
327 advanced cases	42.8 per cent alive
93 recurrent cases	49 per cent alive
9 postoperative cases	88.8 per cent alive

During the past year we have replaced the bare unfiltered radium seeds, formerly used, by gold seeds of 0.2 mm gold filtration which practically shuts off all gamma rays, and we believe this has been a distinct advance in the treatment of the primary lesion

## CONCLUSIONS

1 Hysterectomy as a means of removing the primary lesion may still be done in very favorable cases

2 When hysterectomy is done, it should be promptly followed by thorough postoperative cross fire irradiation of the pelvic field

3 If facilities for proper radiation therapy are available, hysterectomy should not be resorted to in the treatment of carcinoma of the cervix

4 A combination of radium and X-ray therapy seems to be the most efficient form of treatment at present

5 Unfortunately, the vast majority of the patients who develop carcinoma of the cervix will die of the disease because of the difficulties incident to early diagnosis

6 All benign cervical lesions require constant watching until cured

## ANALYSIS OF ONE HUNDRED CASES OF BRONCHO-PULMONARY SPIROCHETOSIS\*

By DAVID T SMITH, M D, † RAY BROOK, N Y

JOHNSON in 1909 (10) and Rothwell in 1910 (29) were the first among American observers to recognize broncho-pulmonary spirochetosis. However, it was not known that the disease is relatively common in this country (Table I) until the contributions of Pilot and Davis (23) and Kline (11, 13, 14)

by me at Ray Brook. The number is not sufficiently large to allow a definite opinion regarding the influence of age, sex and race on the incidence of the disease. In this series, the age varied from 4 to 69 years, the average was approximately 33 years. Its occurrence was three times as frequent in males as in females in the 103 cases in which the sex was noted. The race was reported in 107 of the 126 cases, 94 were in whites of various nationalities, 12 in negroes and one in a Mexican.

For purposes of classification, the cases included in this series may be conveniently divided into 12 groups (Table II). The protean manifestations of the disease are revealed by a glance at this table. The pulmonary lesion in the 85 instances recorded was confined to the right lung in 38, to the left lung in 17, and in 30 both lungs were involved.

TABLE II

- 1 Lung gangrene.
- 2 Lung abscess following tonsillectomy
- 3 Lung abscess following extra-respiratory operations
- 4 Lung abscess complicating neoplasms of the lung
- 5 Lung abscess associated with a foreign body in the lung
- 6 Primary or spontaneous lung abscess
- 7 Unresolved pneumonias
- 8 Acute bronchitis
- 9 Bloody bronchitis
- 10 Putrid bronchitis
- 11 Chronic bronchiectasis
- 12 Any of the above mentioned types associated with pulmonary tuberculosis

## BACTERIOLOGY

Previous studies indicate that a wide variety of aerobic organisms is encountered in this condition, notably the influenza bacillus, streptococcus and pneumococcus. However, the organisms constantly associated with this disease (15) belong to the anaerobic group: the spirochetes of the Vincent type, the fusiform bacilli, the vibrios and the cocci (Table III). This group of anaer-

very unusual opportunity to observe the clinical course of this disease in the patients under treatment at the Memorial Hospital, our problem is not how we shall treat the primary lesion in the early or favorable cases, but how shall we postpone or prevent the almost inevitable recurrence in the parametrium or the lower vagina

Considering only the very early cases, we may dispose of the primary lesion by electrocoagulation, cautery amputation of the cervix, hysterectomy or radium. With any one of these methods the primary lesion may be so thoroughly removed that there will be no local recurrence. Nevertheless, the patient will almost inevitably develop cancer in the parametrium unless further treatment is promptly instituted

To my mind there is no form of therapy today that can compare in value with radium and X-ray in delaying or possibly even preventing the appearance of cancer in the parametrium after the primary lesion has been destroyed in any one of the ways mentioned. Our studies on this point at the Memorial Hospital, we believe are sufficiently convincing to encourage a resort to thorough cross fire irradiation of the entire lymphatic drainage area as soon as possible after the primary lesion has been destroyed

Personally, I believe the entire treatment in the "early" group can be carried out by radiation therapy alone to great advantage for the patient and without resorting to hysterectomy if one has access to proper radium and X-ray facilities

When we turn to a consideration of the borderline and advanced groups, we have an entirely different problem. Here we can say without fear of contradiction that irradiation therapy represents the best and safest treatment from the standpoint of relief of symptoms, prolongation of life and, in some cases, possibly entire elimination of all active disease

Our success in the treatment of these cases will depend upon our facilities for the application of radium in an exact and scientific manner at the primary site of the disease as regards dosage, filtration, types of applicator, etc., and the coincident use of X-ray therapy for the deeper portions of the pelvis

Each patient must be individualized and treated as a separate and distinct case presenting differences in local extent of disease and in constitutional resistance. The total hours dosage of radium used will, therefore, vary according to these factors, as well as the filtration or type of applicator used, and whether or not one is planning to entirely eradicate the lesion or merely to palliate symptoms

Such phrases as therapeutic dose, physiologic dose, trial dose, test dose, etc., as used by some writers in referring to the first dose of radium applied to the cervix are, in our opinion misleading, if not harmful and should be discarded

A proper conception of the gravity of the disease and the urgent necessity for promptly checking it would indicate that the heaviest dose compatible with the integrity of the adjoining normal structures should be used for the first application in order to promptly induce the greatest possible regression at once. This also induces tissue reactions in the adjoining normal structures which we believe are advantageous in limiting the activity of cancer cells

Subsequent applications of radium will depend entirely upon the effectiveness of the first dose and the manner in which it was applied

Previous to October 1, 1921, the gynecologic service was in charge of Dr H C Bailey and the patients were treated with radium only at that time. After January 1, 1918, on the principle of cross firing the lesion and the parametrial structures, radium was applied against the vaginal vault, within the cervical canal and externally about the pelvis

Twelve per cent of all the cases treated in 1918 are still alive and it is interesting to note that five of those cases were in the advanced group. They have nevertheless lived a full seven years since treatment

From January 1, 1922, to date, I have endeavored to adhere to the cross fire method of irradiation, using the maximum primary dose of radium in and adjoining the lesion and supplementing this later with low voltage X-ray externally. Three years have elapsed for all cases treated in 1922 by this plan. There were sixteen early cases of which 68.7 per cent are still alive and well, there were 27 borderline cases of which 37 per cent are alive, 80 advanced cases of which 17½ per cent are alive

There were 29 recurrent cases accepted for treatment in 1922 after having been operated on unsuccessfully in other hospitals, and when they applied to us for treatment, definite palpable masses could be identified in the pelvis and in some instances biopsy to confirm the diagnosis was possible. Of these 29 recurrent cases, it is interesting to note that 31 per cent are still alive. These cases were all treated with radium and X-ray

Taking all cases treated on this plan from January 1, 1922 to date, we have the following results

66 early cases	81.8 per cent alive
68 borderline cases	66 per cent alive
327 advanced cases	42.8 per cent alive
93 recurrent cases	49 per cent alive
9 postoperative cases	88.8 per cent alive

During the past year we have replaced the bare unfiltered radium seeds, formerly used, by gold seeds of 0.2 mm gold filtration which practically shuts off all gamma rays, and we believe this has been a distinct advance in the treatment of the primary lesion

TABLE V  
SYMPTOMS IN 100 CASES

Cough	95%
Expectoration	94%
Rales	63%
Foul sputum	62%
Fever	60%
Pleural pain	52%
Hemorrhage	50%
Foul Breath	30%

Clubbed fingers	13%
Night sweats	12%

exception of foul sputum, they conform to the prominent symptoms in pulmonary tuberculosis. Hemoptysis, the striking symptom in tuberculosis (8) occurs with equal frequency in this disease. Owing to the similarity of the symptoms, the diseases are frequently confused. In 24 of the 126 cases, active pulmonary tuberculosis was eliminated either at autopsy or by a negative tuberculin test (Table VI). In 9 of the 126 cases active pulmonary tuberculosis was a complicating factor.

Proven tubercle bacilli and spirochetes	9	4	44	5	56

### BLOOD

Where the disease was chronic and limited to the bronchi, the blood was for the most part normal. In the parenchymatous lesions, secondary anemia was relatively common and the white blood count ranged between 10,000 and 60,000 with a relative and absolute increase in the polymorphonuclear leucocytes.

The Wassermann Test was recorded in 36 of the 126 cases, it was negative in 33, doubtful in 2 and positive in one.

The physical and Roentgenographic findings showed considerable variation according to the extent and location of the lesion. When the disease was for the most part in the bronchi, the signs were those of bronchitis or bronchiectasis, and little information was obtained from the Roentgenogram unless the exposure was made

following intratracheal injection of lipiodol. This procedure is effective in revealing the bronchial dilatations. In the parenchymatous lesions there were usually signs indicating pulmonary consolidation, and on the chest Roentgenogram the shadows were dense and as a rule confined to one section of the lung field.

### COMPLICATIONS

Brain abscess and empyema were the two important complications (Table VII). Brain abscess was usually fatal while with empyema the prognosis was grave.

TABLE VII  
COMPLICATIONS

Complication	No of Cases	%	Remarks
Empyema	11	11.5	B. fusiformis, spirochetes and streps in all cases
Brain abscess	3	3.1	Spirochetes, B. fusiformis in one.
Hydropneumothorax	2	2.1	No spirochetes in two

### TREATMENT

The results of treatment are summarized in Table VIII. Spontaneous recovery occurred in a limited number of cases. The arsenical preparations were particularly helpful at times when employed early in the disease. When the disease was of six months' duration or longer, no instance was recorded in which the disease was cured. Drainage of the cavities by posture is often attended by striking amelioration of the symptoms. In this series, operative procedures were employed in a limited number, on the whole the results were encouraging. Rest during the toxic period is as essential as in pulmonary tuberculosis.

Total	32	29	31	22

is warranted that they are not merely contaminants, according to prevailing opinion, but are in reality the causal agents of the disease. This view is supported by experimental evidence.

With these organisms, Chalmers and O'Farrell (5) induced bloody bronchitis in a monkey, Pilot and Davis (23), gangrenous lesions in previously traumatized tissues of the rabbit, and Kline (12), pleuro-pulmonary gangrene in a rabbit by intrabronchial inoculation. I have been able to produce lung abscess in mice by the intratracheal injection of washed sputum containing spirochetes, fusiform bacilli and cocci recovered from cases of lung abscess and chronic bronchiectasis. Furthermore, it was possible to produce pulmonary abscess in mice, guinea pigs and rabbits by the intratracheal inoculation of scrapings from the gums of patients suffering from pyorrhea. It is significant that these pyorrhea specimens which produced experimental pulmonary abscess, contained spirochetes, fusiform bacilli, vibrios and cocci that were morphologically identical with the organisms recovered directly from the pulmonary lesions in patients. This observation leads naturally to the conclusion that broncho-pulmonary spirochetosis is probably the result of aspiration, from the mouth into the lungs, of this group of anaerobic organisms.

Fusiform bacilli, vibrios and cocci may be isolated in pure culture by ordinary anaerobic methods for the cultivation of bacteria. Although the spirochetes may be grown by the fresh-tissue-acetic-fluid method of Noguchi, still to date attempts to isolate them in pure culture have not proven successful.

Ordinary analine dyes suffice to satisfactorily stain the fusiform bacilli, vibrios and cocci. The spirochetes are best demonstrated by the Fontana stain. The ammoniacal silver nitrate solution used in this stain deteriorates, and after 5 or 6 days is no longer effective for staining spirochetes. Very thin smears are a requisite. They must be made within the first hour after the specimen is collected because the spirochetes when exposed to the air lose their ability to retain the stain. If, however, the specimen is kept under anaerobic conditions, the spirochetes retain their tinctorial properties for at least 4 or 5 days. Spirochetes are readily demonstrated by the aid of the dark field (Figure).

DARK FIELD PICTURES OF SPIROCHETOSIS

Section 1, represents the spirochetes (*T. macrodentum*, *T. microdentum*, *S. buccalis*, *S. Vincenti*), fusiform bacilli, vibrios and cocci found about the teeth of a patient suffering from moderately severe pyorrhea alveolaris.

Section 2, shows the spirochetes, fusiform bacilli, vibrios and cocci in the pulmonary sputum (after washing) of a patient with a lung abscess. Note the absence of the thick *S. buccalis*.

Section 3, contains drawings of *Treponema pallidum* found in a typical chancre. These organisms are quite different from those in the other sections.

Section 4, is a drawing of the organisms in the bloody sputum of a patient with chronic bronchiectasis. Many thick *S. buccalis* specimens are present.

Section 5, illustrates the spirochetes, fusiform bacilli, vibrios and cocci found in the pulmonary sputum (after washing) of a patient with chronic bronchiectasis. These forms are identical with those seen in Section 2.

### SYMPTOMS

To the varied nature of the pathological lesions in broncho-pulmonary spirochetosis may be attributed the wide difference in the clinical manifestations. The more common symptoms are enumerated in Table V. It will be noted that, with the

## THE DIAGNOSIS OF EARLY DIABETES\*

By F R WRIGHT, MD, F A C P, CLIFTON SPRINGS, NEW YORK

Clifton Springs Sanitarium and Clinic

**A**UTHORITIES claim that diabetes mellitus is on the increase. Joslin (1) estimates that there are a million diabetics in the United States and is of the opinion that a campaign for its prevention holds the same promise as preventive measures against tuberculosis and other preventable diseases. Probably it is true that the diagnosis of early diabetes in most cases is more simple than the diagnosis of incipient tuberculosis. However, more than a routine examination of the urine is needed in this search for the early diabetic, and many so-called prediabetics will escape detection if the routine analysis of the urine is supplemented only by the fasting blood-sugar determination, for there are borderline cases which show a transient glycosuria and do not always have a fasting hyperglycemia. In such cases the test for glucose in the urine may be positive on the first examination, but on the second test, a few days later, glucose is absent. Now, if the fasting blood-sugar varies and is

only occasionally above the normal, the real significance of the transient glycosuria may be lost. In such cases the tolerance of the patient to carbohydrate must be studied before a diagnosis can be made. Glycosuria alone cannot be regarded as pathognomonic of diabetes. Glycosuria is a symptom and its cause must be ascertained in each case. All reducing substances are not glucose, although glucose is by far the most common substance in the urine which reduces the copper reagents.

In the ordinary diet carbohydrate forms more than sixty per cent of the food ingested and yet it probably constitutes not more than one per cent of the body weight. Thus it is seen that sugars and starches are the most easily metabolized of the foodstuffs. So, if the process of metabolism is disturbed, one would expect the disturbance to be manifested particularly in the carbohydrate. The disturbance in metabolism is characteristic of diabetes mellitus and is shown most obviously in respect of that kind of food

\* Read at the meeting of the Seventh District Branch, at Geneva, New York, September 29, 1926

which is eaten abundantly and which forms the smallest part of the body structure

The limit to the amount of sugar which the normal individual can assimilate is sufficiently high for all ordinary needs. One has to take one-quarter per cent of his body-weight (approximately 175 grams for a man five feet, eight inches in height) of glucose at one time before any will appear in the urine under normal conditions. And no amount of starch should cause sugar in the urine, because the time taken in its digestion prevents the blood from being flooded with sugar. While the ingestion of sugar may therefore be followed by glycosuria without implying the existence of diabetes, it is probably a true statement that a glycosuria which appears after a free ingestion of starch indicates diabetes.

When the body begins to lose its power to assimilate sugar, it often attempts to compensate for the loss of valuable foodstuffs by storing up more than usual in the form of fat. Many cases of obesity are merely potential diabetics. This excess storage only adds to the weight of the body, makes activity more difficult and the complete oxidation of the fat makes a greater demand on a system which is already overtaxed. Naturally, there is a limit to this deposit of fat and when this is reached glucose appears in the urine. In still another way the body may attempt to compensate for the loss of sugar and that is by raising the carbohydrate threshold. Routine blood-sugar determination has brought into common usage the term renal threshold, which means the concentration of sugar in the blood at which point glucose first appears in the urine. Normally, the blood contains 100 mgms of glucose per 100 c. c of blood. About twenty minutes after the ingestion of glucose, the sugar in the blood begins to rise, reaches 150 to 170 mgm and begins to fall again toward normal after about one and one-half hours. If the higher figure (170 mgm) is exceeded, one expects to find a positive test for glucose in the urine. But when carbohydrate metabolism has been disturbed for some time, the blood-sugar may rise and yet no sugar appear in the urine. Many diabetics, treated and untreated, show no glycosuria with blood-sugar as high as 250 to 300 mgm or higher—a figure at which the normal individual would inevitably excrete sugar.

This high concentration of sugar in the blood in all probability disturbs the equilibrium of the body fluids and causes many of the symptoms of the diabetic, such as the polyuria and the consequent thirst, the changes in the translucency of the crystalline lens, the neuritic pains brought about by changes in the nerve sheaths, the pruritus, and the liability to furunculosis.

Since the kidney can raise a threshold or barrier to the excretion of sugar and since this threshold can vary in height, it is self-evident that the examination of the urine is not a satisfactory

measure of the blood-sugar. Glycosuria may occur without hyperglycemia, while hyperglycemia need not be followed by glycosuria. The point of interest in cases of disturbed carbohydrate metabolism has therefore shifted from the urine to the blood. A fasting hyperglycemia is indicative of potential diabetes.

As has already been stated, it seems more rational to think of sugar in the urine as a symptom and its cause must be ascertained in each case. With certain patients it may be necessary to exclude disturbances of one or more of the glands of internal secretion and in other cases, the taking of drugs which reduce copper reagents must be eliminated, and in still others, it may be possible to make a diagnosis of renal glycosuria. For a long time, the glucose tolerance test has been used as the criterion in these difficult problems.

In this test comparatively large quantities of glucose are given. As a rule the patient finds it distasteful and is often nauseated. Furthermore, there may be some danger in over-loading a weakened tolerance by the rapid absorption of a large quantity of pure glucose. Also the patient is tortured more or less by having his vein frequently punctured for a specimen of blood and the extra work of analyzing many specimens overtakes a busy laboratory staff.

Many of the patients admitted to this clinic for routine examination have shown transient glycosuria, or have shown symptoms suggesting impaired carbohydrate metabolism such as pruritus, furunculosis, neuritis, substernal pain, etc. The indication in such cases was obviously either to overthrow or to confirm the suspicion that these patients were early or potential diabetics. Because of the objection to the usual glucose tolerance test, it was decided to use a modified glucose tolerance test, or food test—Brill (2).

In this test the night urine is collected and a sample of the fasting blood obtained. A breakfast consisting of 100 grams of carbohydrate, 26 grams of protein and 27 grams of fat is fed, and two hours later a second sample of blood is drawn. The urine excreted during the four hours following the meal is also saved. The sugar content of the two specimens of blood and of the two specimens of urine is determined. By studying the concentration in the fasting blood and the change in the concentration of a specimen taken two hours after the meal, one can gain a fair knowledge of whether the carbohydrate metabolism is disturbed.

In this food test no allowance is made for variation in the emptying time of the stomach or in the rate of absorption from the intestines. It is obvious that such variations may affect the test. However, these same factors enter into the routine glucose tolerance test in which pure glucose alone is given by mouth, also when glucose is given intravenously some is excreted into

the stomach, so that the metabolism is not accurately checked unless gastric analyses be made. Again one might raise the objection that, in this food test as used at the clinic, the maximum blood-sugar concentration is not determined and the complete blood-sugar curve is not obtained. On the other hand minor deviations in such a curve may not be of practical significance and slight or transient abnormalities may be overemphasized. So a method which points to the more marked changes possesses distinct advantages and gives results which can be readily understood.

The cases selected in this problem offered signs or symptoms which suggested some abnormality in carbohydrate metabolism and, yet, the disturbance in metabolism was not sufficient to warrant a diagnosis of diabetes at the preliminary examination. These patients showed transient glycosuria, or were obese, or had neuritis, or suffered from substernal pains, or had furunculosis. This preliminary work covers 268 cases, the number selected from the routine admissions of one year. The majority of signs, symptoms, or accompanying diseases which were found at the time of admission to the clinic are listed in Table 1.

TABLE I

Family history of diabetes	26
Anemia (secondary)	33
Alveolar abscess (chronic)	41
Cholecystitis (chronic)	17
Tonsilitis (chronic)	95
Other infections	35
Arteriosclerosis	17
Hypertension	36
Pruritus	8
Neuritis	22
Neuroses	55
Migraine	8
Thyroid	11
Cardiac	18
Obesity	111
Glycosuria	179

By the modified glucose tolerance (or food) test 81 showed no distinct evidence of impaired carbohydrate metabolism and were considered negative, while 187 showed an abnormal blood-

sugar curve and glycosuria and were classed as positive. Tonsils, teeth and gall bladder accounted for most of the chronic infections, the other infections refer to sinusitis, otitis, media, chronic appendicitis, furuncles, etc. The cases of thyroid disturbance included one colloid goitre, one of the exophthalmic type, and nine cases of adenoma. The eighteen cardiac cases gave a history of substernal pains or showed signs of myocardial weakness.

Forty-five of the cases showing glycosuria were negative according to the test meal, that is, they gave no further evidence of disturbed carbohydrate metabolism. Of the 179 cases of glycosuria, sixty-four gave no history of sugar in the urine previous to the test, but they were selected because of other symptoms and during the food test they were found to have glycosuria and hyperglycemia. Sixty-eight of the series had a normal fasting blood-sugar, but showed a hyperglycemia and glycosuria two hours after the meal.

Since the tendency to diabetes is often concealed for long periods and since, in many instances, the disease manifests itself only temporarily before the cardinal symptoms become permanent, the extreme importance of early detection of these cases cannot be overemphasized. The only hope for the prevention of diabetes rests with the early diagnosis. The diagnosis can be made in the early stage if the first symptoms of a disturbed carbohydrate metabolism are recognized and their real significance determined. The physician who casually dismisses a patient with transient glycosuria, obesity, neuritis, pruritus, substernal pain or furunculosis may find some months later, that the case has developed into one of severe diabetes. In the early cases, the point in the diagnosis rests upon the blood-sugar determination, and in this determination further aid, such as that offered by the test meal, is often required.

## PYELITIS OF FOCAL ORIGIN\*

By M. ZIGLER, M.D., NEW YORK, N. Y.

**M**R. F. J. A., age 32 yrs—married and has one child, 5 yrs old.

Past History—Negative for TBC in personal and family history. 13 yrs ago Gon no complications. Denies syphilis. Past 3½ yrs has burning sensation at tip of penis, present at all

times without reference to urination. For 3½ yrs diurnal frequency 8-10 X, no nocturia. Has received local treatment directed toward urethra, on and off for past 3½ yrs such as sounds, irrigations etc., without any improvement.

Present History—May 4, 1925, came to the office with the following complaints. Four days ago developed increased diurnal frequency, noc-

\* Read at Bronx Surgical Society April, 1926.

turia 1-2 X with pain at end of urination Past 24 hours, three urinations showed total hematuria, other urinations not bloody This day voided cloudy but not macroscopically bloody urine Examination showed external genitals and S V normal Prostrate almost normal Both kidneys gave a negative Murphy sign Kidneys not palpable In view of the fact that the patient had received instrumentation elsewhere, I felt that the condition present was a mechanical and chemical cysto-urethritis and gave him ol santali, Hyoc, and Kal Citras internally and ordered him to drink large quantities of water Patient returned two days later stating that the previous night again had total hematuria associated with fever, chills, sweats and with excruciating pains on urination Examination showed slightly tender palpable right kidney with a positive Murphy Both urines were very pus cloudy (hazy) macroscopically The diagnosis of Pyelitis was now made During all this time the patient complained of very severe pain in muscles of back in sacro-lumbar region, also pain in right shoulder He was now given urotropin and acid sod phosphate A 24-hour specimen of urine was highly acid, probably due to acid sod phosphate and showed a large number of red and W B C, heavy trace of albumen, negative for casts and tubercle bacilli The culture plate showed bacilli coli present Within 48 hours the temperature dropped to normal but the patient still had knife like pains in the perineum Remained in bed 48 hours

May 11, 1925 One week after coming under observation patient was fairly comfortable Temperature taken 6 times this day, found normal each time Urotropin and acid sod phosphate were discontinued Gave patient 30 gr Bicarb q 3 hours because some authorities have stated that a rapid therapeutic change from acid to alkaline or vice versa causes a very favorable influence in pyelitis Within 15 hours after the change, the patient developed his first real chill, heartburn, temperature ranging from 101 to 104 Promptly upon the re-administration of acid sod phosphate the temperature dropped to normal and remained so

Patient remained in bed seven days from date of elevation of temperature Right kidney remained tender and slightly enlarged for about one month Six weeks after onset no urinary symptoms present The pains in the sacro-lumbar region became a great deal worse from the cular pains involved the entire back, no localized area being worse than any other, the thought of 6th to the 10th week after onset As these mus-absorption from the tonsils as a focus entered my mind, especially as the urines were still pus cloudy and also because the myalgia responded partly to aspirin and because now, for the first time I obtained the following history For the past 7-8

yrs patient has had frequent tonsillar attacks About 2 yrs ago patient began to have attacks of severe facial neuralgia, pains in the back of the head and neck, terrific headaches, rheumatic pains in the arms, shoulders and back His doctor advised tonsillectomy

July 22, 1925, I examined his throat for the first time and found very large, swollen and boggy tonsils After this finding, I felt there was a definite relationship between his pyelitis and tonsils

July 25, 1925, performed cystoscopy since I felt that the entire condition had subsided enough to warrant this examination During the acute stage of colon bacillus infection of the bladder, I was very averse to cystoscopic examination feeling that the condition would be very much aggravated by such instrumentation Cystoscope No 24 Fr passed readily into bladder, meeting no urethral obstruction. Bladder wall, sphincter and ureteral orifices normal Supramontane portion of the urethra very red and congested Verumantatum very large and globular in shape Passed No 6 olivary shaped ureteral catheters up into both right and left kidney pelves without any difficulty Injected 1 cc Phenolsulphophthalein intravenously and within 15 minutes dye appeared from both kidneys in equal concentration Phenolsulphophthalein estimations—Right kidney—10% in 15 minutes—Left kidney—10% in 15 minutes Microscopical findings of separated urines—Right kidney urine—few R. B C numerous round epithelial cells, negative for pus cells Left Kidney urine—numerous R. B C, round epithelial cells, negative for pus cells Because of presence of R. B C in separated urines, had complete urine examination shortly thereafter and no pus cells or R. B C were found and urine was negative for bacteria Tonsillectomy performed Aug 15, 1925 Oct, 1925, which was 6 weeks after the tonsillectomy, still had slight lumbago pains occasionally in the morning, but not as severe or persistent as the pains that were present prior to treatment and tonsillectomy

April 10, 1926, which was 11 months after he came under observation, radiographic examination of the urinary tract shows both kidneys to be normal in size, shape and position There is no evidence of calculus in either kidney, ureter or bladder Several days later complete urine examination is negative in every way No pathogenic bacteria found by culture

This case is reported as a case of pyelitis, probably secondary to infected tonsils The reasons for thinking so are the following Patient gave a history of 7-year tonsillar trouble, with absorptive symptoms manifesting themselves the past 3½ years by severe pains in muscles of neck, arms, shoulders, etc, and with vague urinary symptoms for same period Then suddenly an

acute pyelitis with no other factor ascertainable as a possible cause. It is true, however, that the colon bacillus was the only bacteria found in the urine and unfortunately I did not ask that the otologist take culture of the tonsils. However, of additional value might be the fact that Hunner states that a large percentage of cases of ureteral strictures are due to focal infections from teeth or tonsils and if ureteritis or ureteral stricture may result from infections in tonsils why not pyelitis. Also some of the Hunner irritable ulcers or elusive ulcers of the bladder are supposed to be secondary infections in tonsils, teeth, etc.

Hunner, in the *Journal of Urology* of October, 1924, says "It is a common observation that the majority of patients with ureteral inflammation also have inflammation of the trigone and urethra and it is probable that in most instances the three processes are evolved from a common cause."

The above quotation was used because this patient showed congestion of the supramontane portion of the urethra. This congestion was probably the cause of his pain in the urethra prior to the onset of acute pyelitis and that the tonsils were the cause of both. Hunner also states in the same issue of the *Journal of Urology* the following "Knowing the relationship of focal infections to the incidence of ureteral strictures, the history in a stricture patient of severe periodic headaches of a migrainous or neuralgic character always calls for an early consultation with the otolaryngologist to determine whether there be a focus of infection in the tonsils, sinuses or teeth. Experience has shown that one fails to get permanent results in a large proportion of ureteral stricture patients until distant foci of infection have been cared for."

Moreover, George Baehr of Mt Sinai in the April 3, 1926, issue of the *A M A Journal* in a paper entitled "Benign Curable Form of Hemorrhagic Nephritis," gives a summary of 14 cases of hemorrhagic nephritis occurring as a result of

focal infections. German clinicians were the first to report this mild type of hemorrhagic nephritis. Scheedemandel and Volhard are both quoted by Baehr.

Baehr's summary of his 14 cases is as follows: "The disease occurs most commonly in young adults and is characterized by a hematuria, usually macroscopic, which may be painless." "Unlike the common form of the acute diffuse disease there are usually no constitutional symptoms." "That is neither oedema nor hypertension develop at any time during the course." "The hematuria may be persistent or recurrent in the form of brief attacks." "In most instances a definite focus of chronic infection can be discovered usually in the tonsils." "The elimination of such a focus for example by tonsillectomy, frequently results in a temporary but pronounced increased hematuria, followed by gradual but complete disappearance of red blood cells from the urine." "Many of the cases are at first considered examples of hematuria due to surgical conditions in the Gu tract." "Some have undoubtedly masqueraded in the past under the general terms of essential hematuria."

#### SUMMARY

(1) Since focal infections in the tonsils or teeth may be a causative important factor in ureteritis, ureteral stricture and hemorrhagic nephritis, why not in pyelitis. We also know the close association between carbuncle of the body and carbuncle of the kidney. The same is true of peri-nephritis abscess following some skin or chronic bone infection.

(2) This case has been presented with the idea of bringing the possibility of pyelitis of focal origin to our attention, so that not only the pyelitis be treated but also that a focal origin be looked for and eradicated.

(3) This case is also presented to show that the rapid change from acid to alkaline urine does not always work favorably.

### THE ANNUAL MEETING

The Annual Meeting of the Medical Society of the State of New York will be held during the four days beginning May 9, in Niagara Falls. While the date is three months in the future, yet the committees are already hard at work preparing the programs and making the necessary arrangements.

The time is also at hand when physicians should begin to make their plans to attend the meeting.

Niagara Falls is well supplied with hotels, and the local committee of arrangements assures all comers of excellent accommodations. Moreover, the session halls and the places of attraction are within easy reach of the hotel centers.

Keep the date and the place in mind, and plan to enjoy the many sided advantages of the meeting and the meeting place in beautiful Niagara Falls.

## A PRECEDENT FOR THE GRIEVANCE COMMITTEE

Physicians have long felt the need of some means by which they could investigate and arbitrate questions of professional conduct, unhampered by publicity and legal precedents. The censors of the county medical societies were established for that purpose, but local acquaintanceships and feuds prevented their proper functioning.

The precedents for the establishment of a Grievance Committee have hitherto been drawn entirely from the experience of lawyers. It is of value therefore to recite the experience of a county medical society with a Grievance Committee over forty years ago.

The Minutes of the Suffolk County Medical Society for April 27, 1882, contain the following entry:

"Dr E H Hamill moved that a Committee on Grievances be appointed by the Chair, whose duties shall consist in acting in the remission of fines, when excuses are proffered, and all such matters as commonly pertain to similar committees in other organizations. He thought the society would as a body be saved much time, and that it had become a necessity. He moved, therefore, that the President appoint a committee of three members on Grievances to report at the next meeting of the Society. Seconded and carried. The President appointed as such committee Drs R. H. Benjamin, F. Thayer and J. H. Benjamin."

Dr Hamill "also gave notice of intending to bring in a new By-law, viz., 'that a committee of three members in good standing, to be called a 'Committee on Grievances,' be elected annually, whose duties it shall be to consider and report upon all grievances between members and also to consider the propriety of remitting any fine or fines that shall be imposed, under Art II, Sec I of By-laws, and to report upon all other matters that may be referred to it'."

The Minutes of the evening session held the same day record that Dr Hamill made the following charge against Dr A G Thompson of Islip:

"Charge 'For conduct unbecoming a professional brother'."

"Specification 1st 'On or about January 15th, 1882, Dr A G Thompson having been called by myself (Dr E H Hamill), and without request of the patient, to visit in consultation a patient suffering with some obscure malady, probably cancerous, came probably on two or three occasions at different times, on being again invited by myself without request of the family, he informed me that he had just returned from a visit to patient and family, and had advised them to secure the services of another physician, mentioning Dr J R Mowbray of Bay Shore

I, within a few minutes, asked him if he had done this of his own accord, he replied he had'."

"Specification 2d 'That after a consultation with Drs Mowbray, Vandewater and myself, at which he (Dr A. G. T.) was not present, he repeated in public that a consultation had been held, that the man now had some chance for himself, and that my drugs had been thrown out of the window, or words to that effect'."

"Specification 3d 'That after the decease of the patient, and at the funeral, he accompanied the clergyman as the attending physician, preceding the hearse, to the burial ground or cemetery, notwithstanding the fact that the family had requested that I should do so'."

Specification 2d was changed on May 9 to read "That, after a consultation, Drs Mowbray, Vandewater, and I being present, he (Dr Thompson) was heard to say publicly that 'we had held a consultation, that the treatment had been entirely changed, and that the man now had a chance for recovery'."

The charges were referred to the Committee on Grievances, which made an unrecorded report on October 31, 1882, but the report provoked much discussion, and it was referred back to the Committee.

The final report of the Grievance Committee was made to a meeting of the Society on April 29, 1885, and was as follows:

"As members of the Committee on Grievances, appointed at a meeting of the Society held the 29th day of April, 1882, and the addition of Dr A B Luce, Nov., 1882, we have had submitted to us charges against Dr A G Thompson by Dr E H Hamill, the latter charging A G Thompson with conduct unbecoming a professional brother. We have examined each of the specifications enclosed in this report separately and find as follows:

"In regard to the first specification, we find the explanation made to us in writing by Dr A G Thompson of that character as to exonerate him from all censure.

"As to the charge in the second specification the only part proven is that Dr Thompson said there had been an entire change in the treatment, and there was a chance for recovery. As we understand the testimony, both Dr Hamill and Dr Thompson admit both the testimony and the inference. Courtesy was, we think, that if Dr Thompson could not have added at the same time, *that the past treatment had been judicious*, he should have left it to the attending physician to have announced the change of treatment.

"In regard to the 3d specification, we do not consider the rules of medical etiquette at funerals sufficiently established as to cause the alleged

deviation at the time worthy of professional censure

"We therefore affirm that the errors alleged committed were of so trivial a nature as to be unworthy our censure

"R H Benjamin,

"J H Benjamin,

"A B Luce,

"Committee

"Riverhead, N Y, Oct 25, 1884"

The principal actors in this case were prominent physicians. Dr A G Thompson was born in New York in 1816, graduated from the College of Physicians and Surgeons in 1837, and was Secretary of the New York Medical and Surgical Society. He practiced in Islip from 1851 to his death in 1887. He was prominent

in both medical and civic circles, was a frequent attendant at the meetings of the Suffolk County Medical Society, and was a member of the Assembly in 1857.

Dr E H Hamill was of southern birth. He was licensed in 1868, and practiced in Islip until 1887, when he entered the employ of the Prudential Life Insurance Company, and became its Chief Medical Director.

The three members of the Grievance Committee were all honorable physicians practicing in Riverhead.

There does not seem to have been any further entry regarding a Grievance Committee in the minutes of the Suffolk County Medical Society.

The JOURNAL will print any other references to a grievance committee or a similar committee which may be discovered.

## NARCOSAN AND THE NEWSPAPERS

A brief semi-popular report of a drug addict treatment in a medical journal.

A "news release" of the same story given out before the date of publication of the medical journal.

A feature story published all over the United States.

An exposure of the record of the originator of the treatment by the Journal of the American Medical Association, which had refused the article which appeared in the Medical Journal and Record.

The condemnation by the State Department of Health of the unscientific conditions under which the treatments were conducted.

An acceptance by the daily press of statements of patients, nurses and interested doctors as being of equal value with the careful medical investigation of the conditions under which the treatments were given.

All these points are discussed in the Department of The Daily Press on page 144 of this Journal.

There is a further point involved in an editorial suggestion by the *New York Sun* of January 17, 1927, which says "The *Sun* would like to see the medical moguls of State and City lay aside suspicion and hair-splitting ethics, and collaborate without delay in a study of the narcosan treatment in the island workhouse."

The medical men who investigated the treatment followed the standard procedure which is dictated by both science and law. When a new subject comes up, the procedure of both the research worker and the lawyer is to examine the evidence and see whether or not it is reliable and founded on accurate observation.

First, as to the discoverer, the American

Medical Association has his record for years back which shows that he is not a physician, but that he is a seeker after recognition on insufficient grounds.

Second, as to the drug itself, the Research Department of the American Medical Association had investigated the product months or years ago and refused it recognition on the ground that its composition was unknown and uncertain.

Third, as to the conditions in which narcosan or similar substances are curative, its promoter has claimed that it is good for cancer, and for addiction to alcohol and veronal. The claims are too broad.

Fourth, as to the application of the treatments on Welfare Island, the representatives of the State Department of Health visited the wards of the patients and found that the treatments were given under conditions of inaccuracy, which seriously impair their scientific value. The claims of the promoters of the drug are their own opinions rather than the logical deductions from the observation of trained observers.

A fundamental principle in law is that legal action must be based on sufficient evidence. A district attorney, for example, investigates complaints and clues, and rejects a far greater number than he prosecutes.

Similarly, the representatives of the medical profession have investigated the claims of the promoters of narcosan and report that the evidence is insufficient to warrant further action.

However, this by no means ends the investigation by physicians. The problem involves an investigation of the entire field of lipoids, vitamins, and specific proteins concerning all

of which our knowledge is only crude. The meager evidence concerning the narcosan treatments already given will be preserved and clues followed up by workers in numerous laboratories. Months and years of investigation will be required to ascertain the composition of the drug and to measure the effects of its constituents on the body. The estimation

of the value of lipoids and vitamins and specific proteins may safely be left to physicians and research investigators working in their own scientific way. The reports will not be given to the newspapers, but to medical and scientific journals whose pages are open to the representatives of newspapers and to any other persons who care to consult them.

## BETTER INSTRUCTION IN PHYSIOTHERAPY

Almost forty years have passed since such medical pioneers as the late Professor Baruch of Columbia University, William J. Morton, also of New York, and Professor Herdman, of the University of Michigan, among others, began their efforts to awaken our American profession to the urgent need for adding scientific physical methods to its other treatment facilities. Dr. William Benham Snow and Dr. Frederic deKraft of New York, in that early group, are still actively engaged in this good work. Recognized leaders abroad, among them d'Arsonval, Oudin, Leduc, Finsen and Winternitz, should also be mentioned here, while such eminent non-medical American scientists as Elihu Thomson, Charles Lorenzo Clarke, Nicola Tesla, and Arthur Edwin Kennelly, helped materially to place the new knowledge on a firm basis. These honored names by no means exhaust this worthy list.

When, therefore, disabled veterans in our late war hospitals required such physical therapy, there were at hand a limited number of fully trained physiotherapists to take charge of special clinics arranged there for their relief. The often astonishingly good results obtained in seemingly desperate conditions proved educational for many physicians, then army officers and stationed at those hospitals. The resultant nationwide call for instruction in these methods found our medical schools lagging, which led directly to one-week courses by peripatetic medical lecturers, either covertly or openly financed by makers of medical electric machines.

Such *ex parte* talks, indeed, served but to whet the taste for more knowledge on the subject so that, in addition, so-called congresses on physiotherapy have been held lately, largely in the midwest, but also arranged by the instrument makers and open to the same objections. These "congresses" show up pitifully when compared with the highly technical proceedings of like international physiotherapy

meetings in Europe. The Council of Physical Therapy of the American Medical Association has just issued its disapproval of such courses (*JAMA*, Oct. 16, 1926) and, it is understood, will in time issue definite study curriculums for the purpose.

With the intention of aiding this desirable object by offering practical suggestions from members with years of experience in this field, a combination has been effected of committees from the four national or regional organizations representative of this activity. Initial steps were taken by the American Electrotherapeutic Association at its recent Atlantic City meeting and by the American Academy of Physiotherapy at its annual meeting in New York. Since then the American College of Physical Therapy and the Western Physiotherapy Association have joined in the movement. The committee of the first named society includes Dr. F. B. Granger, physician-in-chief, physical therapy department, Boston City Hospital, and lecturer on the subject at Harvard University, Dr. B. B. Grover, lecturer on the subject, Western Physiotherapy School, Colorado Springs, Colo., Dr. W. T. Johnson, lecturer on physiotherapy, University of Pennsylvania, Philadelphia, Dr. Disraeli Kobak, lecturer on physiotherapy, Rush Medical College, Chicago, and A. Bern Hirsh, New York City, chairman.

Stanford University has this year made physiotherapy an obligatory subject in the undergraduates' teaching course, and the other medical schools must soon follow.

When the Council on Physical Therapy shall have completed (1) its postgraduate curriculum for physicians wishing to add physiotherapy to other treatment methods, and also (2) a training course for non-medical physiotherapy technicians, preferably in hospitals, there can no longer be any reason why the newer measures should not be utilized by the profession everywhere.

## TUBERCULOUS INFECTION

A physician attending the New York Tuberculosis and Health Conference in the Hotel Biltmore, New York City, on January 19 and 20, could not fail to receive valuable information regarding the modern conceptions of the medical problems involved in the care of tuberculosis. This conference was held under the joint auspices of eight health organizations, four of which were medical—the Medical Society of the State of New York, the Departments of Health of the State and the City of New York, and the United States Public Health Service. The lecturers spoke largely on medical topics, and in a style suited to physicians, although a large majority of the audience were ladies. The speakers left the impression that the control of tuberculosis is a problem in infectious diseases, and is to be handled as other communicable diseases. Infections occur in early adult life more often than in infancy and childhood, and effective prevention consists in the

detection and control of the disease in its incipient stage before the bacilli are scattered to other persons. This is a medical activity and must be conducted by physicians.

These statements are commonplace, and have been repeated so often that they fail to impress physicians generally. But in addition to the older knowledge, experience has taught the specialists in tuberculosis that many of the rosy promises regarding the annihilation of the disease are not coming true, and that the methods of the past have been insufficient. The past five years have seen a clarification and a simplification of medical views regarding the disease. Definiteness is replacing beliefs, and standardization is taking the place of empiricism.

When physicians find the modern viewpoints set forth with definiteness, they will take up tuberculosis control with the interest which the situation demands.

---

## MEDICAL LEGISLATION

The annual session of the Legislature is well under way, and medical bills are slowly materializing. An anti-vaccination bill has been introduced, as also have nine workmen's compensation bills that were introduced last year.

The plans of the chiropractors are not yet disclosed, but a delay in showing their hands is a part of their usual strategy. Their next move

will probably be dependent on the action of the legislative committee to investigate chiropractic, of which two hearings were reported in the last issue of this Journal.

While the Medical Society of the State of New York is not actively sponsoring any major bills, as in years past, yet it must keep up an attitude of alertness in the defense of public health.

---

## LOOKING BACKWARD

### THIS JOURNAL TWENTY YEARS AGO

*Methyl alcohol in drugs.* There is nothing new under the sun, even the adulteration of ethyl alcohol with methyl alcohol. Twenty years ago the substitution of wood alcohol for ethyl alcohol was practiced even in pharmacy—something which is probably not true today.

This Journal for February, 1907, has an article on "Substitution and its Remedy," by Dr. Clinton T. Brandow, of Locke, N. Y., which contains the following quotation from a letter of the New York City Board of Health:

"The next inquiry was the alleged use of methyl (wood alcohol) in the preparation of tinctures, in the place of ethyl alcohol as required by the United States Pharmacopoeia. Among the samples of spirits of camphor, several were found to have been prepared with methyl, or wood alcohol. Examinations of samples were, therefore, continued

"In all, two hundred and fifteen samples were collected and examined. Of these, one hundred and seventy-five were properly prepared with ethyl alcohol, while forty contained methyl alcohol. In thirty of the latter, methyl alcohol has been used exclusively, no ethyl or grain alcohol being present. Ten contained both ethyl and methyl alcohol.

"Five of the adulterated samples had 'For external use' printed in small type on the label. Three, on the other hand, had printed directions for internal use on the label, as follows: 'Dose, from five drops to a teaspoonful, first added to sugar and then mixed with water.'

"These three had been prepared with methyl alcohol exclusively. The remainder were simply labeled 'Spirits of Camphor.'

# MEDICAL PROGRESS

**Tetanus in the "Barefoot Boy."**—The author, A. Konigsweiser, does not take up the incidence of tetanus in all those who go barefoot in the summer, but the supervision of the disease after operation on the sole of the barefoot boy. He gives three case histories of post-operative tetanus in youths from 10 to 17 years of age in which the operative technique had been faultlessly aseptic. In the first patient there had been no accidental injury but an orthopedic intervention for a sequel of infantile paralysis. Lockjaw set in on the 12th day and ended fatally within 24 hours despite antitoxin and magnesium sulphate. The other cases were of the same character. In the second case tetanus developed on the 8th day with death four days later. In the third case the disease developed on the 6th day and again death occurred inside of 24 hours. Many similar operations in the clinic along this time were without any tetanus complication and the only bond between the three fatalities was the fact that the victims went barefoot. The observation period covered was about four years. The technique of asepsis before operation had included careful cleansing of the soles with soap followed by iodine tincture.—*Muenchener medizinische Wochenschrift*, October 8, 1926

**Treatment of Seasickness with Inhalations of Oxygen**—Dr. Weiss, a ship surgeon, states that in his experience there is no certain remedy for seasickness. Like all of his colleagues he is glad to test any newly recommended treatment and thus he included a trial of oxygen supplied free by a maker. He tested some of the worst cases, in which the patient vomits continuously, for here there is no chance to give drugs by the mouth. He tried inhalations of oxygen, and the patients found therefrom a certain amount of relief from the incessant vomiting, so that it became possible to give the usual remedies by the mouth. The author gives usually a mixture of quinine, valerian, spirit of ether, and rhubarb, at times with opium addition, which gives considerable relief, and this in association with the oxygen inhalations has proved quite satisfactory. He does not claim any striking improvement from the oxygen, no freak cures of seasickness, but thinks the remedy might save life in the subject with peptic ulcer, peritonitis, etc., who must now and then be found as a passenger on the large liners. He would like his colleagues in various parts of the world to make a trial of it.—*Muenchener medizinische Wochenschrift*, October 1, 1926

**A Combination Treatment of Whooping Cough**—W. Buttermilch, of the Berlin Nursing Home, states that but two methods of treatment of this affection are in common use and with general endorsement, namely, the fresh air and the Czerny suggestive method. Since the latter cannot be used until after the fourth year it may be left out of consideration for those below that age, when pertussis is most dangerous. Especially in institutions for nurslings it is desirable to have in readiness a method for general use and early in the outbreak. A sedative of some sort is indicated, and in the attempt to produce an emulsion of bromoform for routine use the author casually tested cod-liver oil rich in vitamin. The results were astonishing, and although the author was at first concerned with the treatment of children under the age of two years and in the incubative and catarrhal periods, benefit was seen in older children and in the convulsive stage. Thus far the number treated is 86, of which over half were under two years of age. Benefit was sometimes seen in the first two or three days, but as a rule not until the fifth or sixth day. There was but one death among the very young children, a boy of seven months succumbing to bronchopneumonia. Results show that treatment should be begun at the earliest moment possible with the dose as large as can be tolerated. The author makes suggestions as to why the oil is of such benefit, for the results cannot be ascribed principally or solely to the bromoform. He suggests that the vitamin in some way augments the resistance to the disease, as by affecting the mineral metabolism and antagonizing a predisposition to rickets and spasmophilia. The convulsive component appears to be actively antagonized by the treatment.—*Deutsche medizinische Wochenschrift*, November 5, 1926

**Obscure Pyrexias of Childhood.**—James W. Bruce, writing in the *Therapeutic Gazette* November, 1926, n s 1, 11, states that because of the difficulties of diagnosis in young children, doctors are frequently tempted to assign teething and indigestion as causes of fever when further examination might have revealed something else to which the fever was secondary. There are three diseases common in young children which are liable to be overlooked because they show no localizing symptom or sign. These are lobar pneumonia, pyelitis, and otitis media. *Lobar pneumonia* can be, and frequently is, a silent disease. Its onset is commonly not as sudden as in adults, the

initial chill is rarely seen, the cough is not distressing, and often is so mild as not to attract attention until the fifth or sixth day when it becomes an outstanding feature. Dyspnea and a pulse-respiration rate of  $2\frac{1}{2}$  or 3 to 1 can often be seen in high fever from any cause. In pneumonia many children are dyspneic and show the 4 to 1 ratio. Pain in the side or chest is more frequently absent than present. Physical signs of consolidation are nearly always late in appearing—often not until the day before or the day of the crisis. The signs do not involve the entire lobe, but can only be heard over an area the size of a silver dollar. The prognosis of lobar pneumonia is better in childhood than in later life. *Pyelitis* is so common in little girls that repeated uranalysis should be made in all cases of fever in this sex, which lasts more than two or three days and for which no obvious cause can be found. In the treatment of *pyelitis* the writer has had no success with methenamine and prefers the straight alkaline treatment to the alternating use of acid and alkali. In *otitis media* pain is usually an outstanding feature, and the child screams continuously. However, children under 3 years of age can rarely localize their pains and nothing but an examination of the ear-drums will reveal the cause of the distress. Acute *otitis media* is so common following nose and throat infections that routine examination of the ear-drums should be practised in every child with fever unless some other very obvious cause can be found.

**Diet in Pregnancy**—L. V. Friedman reports a clinical investigation in which the item of weight was followed exactly as other items are followed during pregnancy. If the weight was normal the expectant mother was instructed on the importance of keeping it so. She was urged to limit herself to one moderate helping of each dish but not to skip a meal, which custom it was found was always associated with a rapid gain in weight. If at the end of a month the patient had gained less than one-half pound per week (an arbitrary amount selected from these experiences) she was encouraged to eat more, but if she gained more than one-half pound per week, she was put on a strict diet, which eliminated all sweets, potato, macaroni, soup, but permitted two tablespoonfuls of cereal once a day and one slice of bread per meal. She was told to report once a week and the diet was then increased or decreased according to results. An ample calcium and vitamin content was provided. As a result of this plan, patients who were overweight showed a prompt improvement in comfort, there being less gas, less hyperacidity, and more physical activity. One unexpected find-

ing was the essentially stationary weight during the last four weeks. Patients who were not allowed to gain more than one-half pound a week from the twelfth to the fortieth week showed a marked decrease in the length of the first stage of labor with coincident diminution in the number of operative deliveries. With a slight, but definite decrease in the weight of the baby, there is less likelihood of birth injuries and less chance of postpartum hemorrhage. There is the possibility that a sharply restricted diet may lessen vitality and increase anemia though such results were not noted in this series. These conditions should be watched for, and if they tend to appear the diet should be regulated accordingly.—*Boston Medical and Surgical Journal*, November 25, 1926, cxcv, 22

**The Immediate Prognosis of Major Operations**—Octave Charles Cassegrain, in an article in the *New Orleans Medical and Surgical Journal*, December, 1926, lxxix, 6, endeavors to lay down facts helpful in making a correct prognosis in major surgical operations. He asserts that too often the patient is inadequately studied before operation. An individual may be said to be in good condition for a major surgical operation when the heart, kidneys, and blood are normal, or vary but slightly from the normal. The usual routine examination of the heart omits one point which gives the most information concerning that vital tissue, the myocardium, namely the estimation of pulse pressure. It is generally accepted that when the systolic pressure is below 100 operation is dangerous, it is equally dangerous to operate upon a patient with a pulse pressure of 80 or over, since this indicates that the myocardium has lost a great deal of its reserve strength. In determining the condition of the kidneys, it should be remembered that the chemical and microscopical examination of the urine may give practically normal findings and yet the kidneys may be performing but a small percentage of their normal function. A blood chemistry examination for nitrogen retention is a much safer guide. When the urea-nitrogen rises to 75, operation carries a decided risk—the higher above 75 the greater the risk. The estimation of creatinin is just as important. A rise of creatinin above 3 is of bad prognostic significance. Acidosis is indicated by a lowering of the blood sugar and of the carbon-dioxide combining power, while in the alkaline group the carbon-dioxide combining power is high and the chlorides are greatly reduced. Before operation is undertaken these investigations should be included, and when they vary from the normal (80 to 120 mg for blood sugar, 560 to 650 mg for chlorides, and for carbon-dioxide

combining power 50 to 60) an effort should be made to establish a normal balance

**Mechanical Derangements of the Joints—**Melvin S Henderson reviews the various mechanical derangements which are most common in the joints—slipping of the peroneal tendon, injuries to the semilunar cartilage in the knee, loose cartilaginous bodies in the knee, hip, elbow, or shoulder joint, habitual dislocation of the patella, "snapping of the hip," "trigger finger," habitual displacement of the lower extremity of the ulna inwardly and posteriorly in injuries to the wrist, and habitual dislocation of the shoulder. In the last named derangement, capsulorrhaphy, as usually performed, is followed by 50 per cent recurrence. On the theory that if the head of the bone can be prevented from traveling inward, dislocation will be prevented, Henderson is now using a tenosuspension method in which the head of the bone is suspended to the acromion process by the aid of a free graft made from the peroneus longus tendon. The tendon is placed through the holes bored in the acromion process and the head of the bone. It is pointed out that the peroneus longus tendon is not essential in its original position, its functions being carried on by the peroneus brevis and it makes an excellent piece of tissue for an artificial ligament. In habitual slipping of the peroneal tendon, this structure should be replaced in its groove, and a flap of periosteum and fibrous tissue turned down from the fibula and sewed to the os calcis. Osteo-cartilaginous bodies in the joints are readily diagnosed by the x-rays, and should be removed. For dislocated patella, the operation of choice consists in transferring the insertion of the quadriceps inward, so that on contraction it will have a tendency to pull the patella inward. In "snapping of the hip," which is the result of slipping forward of the trochanter along the margin of the tensor fasciæ femoris, the operation consists in cutting down on this fascia, dividing it, and sewing the lower part of the fascia behind the trochanter. This, however, is not very satisfactory because of the difficulty of finding the lesion that is back of the complaint. Habitual displacements of the lower end of the ulna inwardly and posteriorly may be prevented by drilling holes transversely through the lower end of the radius and ulna and slipping a free strip of fascia lata through the holes, thus forming an artificial ligament. In dislocation of the head of the radius, excision of the head is the only method of relieving the symptoms. In acromioclavicular and sternoclavicular dislocations, strapping is of no benefit, if this luxation causes discomfort recourse must be had to open operation—*Annals of Surgery*, December 1926 lxxxiv, 6

**Overlooked Syphilis—**H Hecht relates a number of cases of mistaken diagnosis from which he concludes that serodiagnosis should be practised in routine. The first patient mentioned had a swollen gland beneath the chin. Later a primary lesion of the lip became evident, but at the first diagnosis this had been somehow overlooked. The diagnosis of the gland as tuberculous by an expert in tuberculosis led to an intensive treatment for tuberculosis before the appearance of the roseola. The second patient showed a gangrenous lesion of the palate which was pronounced due to the Vincent symbiosis. As the treatment—neosalvarsan injections—applied equally to both diseases no great harm was done, the lesion disappearing, but later developments showed that the lesion had been a gangrenous chancre. The third patient showed nodules on the nose diagnosticated as lupus after a negative Wassermann. An ulcer formed and healed under lupus treatment (x-ray, cautery), but recurrence proved it to be syphilitic. The fourth patient presented sores in the mouth which were touched with nitrate of silver apparently without any diagnosis. Healing did not follow and it was only by accident that a physician not in attendance chanced to recognize the true condition of the patient. The latter was about to be married and his bride narrowly escaped infection. The fifth patient was of the same type. In his case, as doubtless in the preceding, some sores in the mouth were held to be harmless aphthæ, but were found to be mucous patches. A newly-married young woman developed a headache which had been regarded and treated as neuralgic. Later there were found abundant evidences of recent syphilis. Of interest is the fact that the syphilis of the husband went back fifteen years. Another patient also had violent headache with fever and a vague rash. No diagnosis was made for a month. The author reports also five other similar cases—*Deutsche medizinische Wochenschrift*, November 12, 1926

**Is the Decline in Syphilis Due to Arsphenamine?**—Professor J Jadassohn of Breslau, has sent out a questionnaire which covers most of Europe in reference to the prevalence of syphilis and the causes of the apparent decrease in frequency. He received 97 per cent of replies. In 14 European countries the syphilographers are unanimous in the statement that syphilis has fallen off in frequency in the past 10 or 15 years. In Italy, Russia, and Bulgaria the full evidence is lacking or opinion is divided, so that these countries cannot be included. In France there was a very marked decline between 1919 and 1923 although the figure has since increased somewhat. Jeanseme appears to have been convinced that the

marked decline was the result of the use of salvarsan while the recent rise has been due to the substitution for salvarsan of bismuth. The decline is best seen when we compare the war and postwar periods with the present time. Thus in Sweden there were 1941 new cases in 1913, the number having risen in 1919 to 5827, to drop to 676 in 1925. In Belgium, Holland, and Sweden the decline has been 75 to 80 per cent which is much greater than in any other country. Even the least pronounced improvement amounts to 25 to 30 per cent as found in Hungary and Norway. No figures can be obtained for metasyphilis. That the improvement cannot be due to moral factors appears from a study of the gonorrheal incidence which shows no corresponding betterment. There is a consensus that salvarsan has been a marked factor in the decline of syphilis, but not the sole one, others comprising education of patients, education of physicians, and better facilities for treatment, which are differently valued by different observers. — *Klinische Wochenschrift*, November 26, 1926

**Diabetes Resistant to Insulin**—F Keller speaks of the numerous cases of diabetes which resist insulin treatment, although the proportion cannot be very large for the author found only one such case in a material of 71 treated. The term resistant must be carefully defined, for the author uses it in the absolute sense while others refer only to a relative refractoriness which requires that large doses be given to get results, there being but little response to ordinary doses. There is also a temporary resistance, as for example when some transitory factor works against insulin such as large quantities of garlic taken with the food, or when the patient is under the influence of adrenalin, thyroxin, or pituitrin, all of which antagonize the action of insulin. In the author's case there was nothing to account for the absolute refractoriness of the patient to the drug in question. There was no evidence that the other hormones were opposing the insulin, but in the absence of any evidence pro or con, the author was inclined to believe provisionally that certain endocrines antagonized the insulin even if the other manifestations of disturbed hormonal activity were latent. The patient who was a young subject, had a typical case of severe youthful diabetes with acidosis, and neither the amount of blood sugar nor the acidosis could be modified by even 110 daily units of Lilly's insulin. The author did not persist with the drug for fear of injury to the patient. During the brief insulin cure no special diet was ordered, but after the first failure of the treatment the patient was placed on strict diet with fasting periods. The urine could not be cleared up and the great daily

fluctuations in the amount of sugar without apparent cause placed the case among the paradoxical glycosurias. The Hungarian preparation of insulin gave no better results although both of the makes mentioned had acted perfectly in other cases.—*Wiener klinische Wochenschrift*, November 25, 1926

**Atypical Glaucoma**—James B Stanford finds that the typical text-book case of glaucoma is the exception rather than the rule. The usual signs—increased intra-ocular tension, dilated pupils, shallow anterior chamber, dilated episcleral veins, wide and deep excavation—are seldom all present, at least not until late in the course of the disease. In some cases it is impossible to demonstrate intra-ocular tension and repeated tests should be made with the same instrument. A tension higher than 15 to 26 mm mercury with the Schiotz tonometer should be regarded as suspicious. If one waits for the anterior chamber to become shallow, or for a deep and wide excavation, the patient will suffer considerable or even irreparable loss of vision. Dilated episcleral veins, though likely to be present, may be absent. Pallor of the disc is an early sign. Contrary to the text-book teaching, glaucoma frequently occurs in young people. In some cases, especially those with acute exacerbation, it is well to look for signs of uveitis. All patients in whom mydriatics have been used for long periods should be watched for symptoms of glaucoma. Arterial and venous pulsations are the exception rather than the rule. In early cases the history must be carefully considered. The anterior segment of each eye should be studied in comparison one with the other, refraction should be determined, loss of accommodation and the change of latent into manifest hyperopia should be investigated, the diameter of the cornea should be determined, the condition of the media examined, and also the condition of the fundus and disc, the tension, and the perimetry of the whole field. In the matter of treatment, the teaching has perhaps been misleading. One would gather that iridectomy in acute glaucoma and miotics in glaucoma simplex would cure these conditions. The multiplicity of operations is proof that none is satisfactory, and miotics probably prevent many cures. When patients are being treated with eserine or pilocarpine they should report once a month for observation and examination. The young oculist should try the procedures which have been most successful on a series of cases to determine which are most successful in his hands and should then limit himself to the use of two or three of these methods.—*New Orleans Medical and Surgical Journal*, November 20, 1926, LXXIX, 6

# LEGAL

By LLOYD PAUL STRYKER, Esq  
Counsel, Medical Society of the State of New York.

## THE GRIEVANCE COMMITTEE GETS UNDER WAY

The Grievance Committee has begun to function. With a full consciousness and understanding of the high responsibilities entrusted to them, with an anxious desire to meet and solve the delicate and difficult problems committed to their charge, and with a firm determination to justify the high hopes with which the idea was conceived, the members of the Grievance Committee have begun their work.

Upon nominations made in pursuance of the statute, the following Committee has been appointed:

Orrin S. Wightman, M.D., New York, Chairman

Frederick H. Flaherty, M.D., Syracuse, Secretary

Allen A. Jones, M.D., Buffalo

Moses Keschner, M.D., New York

Grant C. Madill, M.D., Ogdensburg

William S. Overton, M.D., Binghamton

Martin B. Tinker, M.D., Ithaca

Roy Upham, M.D., Brooklyn

Arthur B. Van Loon, M.D., Albany

Roy Williams, D.O., Rochester

The statute authorizes the Chairman of the committee to designate three or more members of the committee, including at least one member who represents the same school of practice as the physician against whom the charges are preferred, to hear charges and report thereon to the committee. Acting in pursuance of the statute, four sub-committees were appointed for the convenience of hearing cases. These are as follows:

A western group consisting of Dr. A. A. Jones, of Buffalo, Dr. Ralph Williams, of Rochester, and Dr. M. B. Tinker, of Ithaca.

A Mid-State group consisting of Dr. G. C. Madill, of Ogdensburg, Dr. F. H. Flaherty, of Syracuse, and Dr. W. S. Overton, of Binghamton.

An East-Central group consisting of Dr. Arthur B. Van Loon, of Albany, Dr. F. H. Flaherty, of Syracuse, and Dr. W. S. Overton, of Binghamton, or Dr. G. C. Madill, of Ogdensburg.

A Southern group consisting of Dr. O. S. Wightman and Dr. M. Keschner, of New York, and Dr. R. Upham, of Brooklyn.

There can be no doubt from the personnel of this committee but that the rights and privileges of the medical profession are in safe hands.

These doctors, from their long experience in the medical profession and from a thorough acquaintance with its difficulties and its problems, will face the task which the statute has committed to them with a firm desire and ample capacity to do justice in any case which comes before them. They will bear in mind that it was for the protection of the doctor, fully as much as for the protection of the patient, that this tribunal was conceived, set up and instituted. No one will be quicker than they to discriminate between unwarranted and baseless charges on the part of patients unjustifiably critical, and those which contain real merit.

No doctor honorably practicing his profession in this state need give himself the slightest concern but that any unjust, unfounded charge which may be preferred against him will receive the dismissal that it merits. On the other hand, every honorable practitioner may take a new pride in his profession which comes from the consciousness that its standards will be upheld and that any doctor who is disgracing his profession and thereby bringing the whole healing art into disrepute, will be dealt with by this committee as he deserves.

With the creation of this committee we now have a self-governing profession—a government of doctors by doctors and—in the largest and most equitable sense—for doctors. The idea upon which this tribunal was conceived and the personnel which has now been chosen are such as will and should meet with the cordial approbation and the sincere confidence of every member of the medical profession. Even those who were originally opposed to this plan, as they observe the careful, considerate and just manner in which it is now being carried out, will (in the opinion of the writer) ultimately add their approbation to that of those who conceived it.

There is no profession more tenacious of its good name or more justly jealous of any infringement upon its prerogatives than the medical profession. There is nothing about the Committee on Grievances, its personnel, its jurisdiction, its scope or its actual operation which need give anyone concern or cause to fear that the valued liberties, privileges and rights of the medical profession will be invaded.

Several misconceptions of the nature of the committee's work have been brought to our attention. One of these seems to be that the Grievance Committee itself initiates charges against physicians. This is not true. The Grievance Committee neither does, nor has it power to, initiate charges against anyone. The statute is very clear that charges may be preferred "by any person, corporation or public officer." The Regents are likewise given power to initiate them, but the committee itself does not and cannot. The duty and authority of the committee begins and ends with its jurisdiction to hear and determine charges against duly licensed physicians.

The charges which the Grievance Committee may hear are those for violation of the provisions of Section 174a of the Public Health Law, except subdivision 1 of that section. The matters which come within its jurisdiction are those pertaining to charges of (a) fraud, (b) conviction for crime, (c) habitual drunkenness or drug addiction, (d) fraudulent advertising, etc., and (e) abortion or unlawful contraception. It is for the hearing and determination of charges embracing one or more of these accusations that the committee is vested with authority.

Any physician against whom charges are preferred, especially if they are unjustly preferred, quite naturally entertains a feeling of annoyance (perhaps this word is not strong enough). But every physician who unfortunately finds himself in that position and who knows that the charges are without merit and that he has not committed any of the prohibited acts coming within the jurisdiction of the committee, may enjoy that feeling of security and peace which should come with the consciousness that the charges will be heard by a committee of his peers, by members of his own profession, who will understand his problems and be sympathetic with his difficulties. If he has not done any of the prohibited acts, he need not fear but that he will be given a complete and perfect opportunity to prove his innocence.

The underlying theory of the Grievance Committee plan was not only to protect the public, but fully as much to protect the doctor. To the accomplishment of this end the committee was vested with considerable discretion. If, for example, the charges are of such a nature as, in its opinion, are insufficient to warrant even the holding of a hearing, it has power to dismiss the charges without putting the accused doctor to the burden, the annoyance or the difficulties of a trial.

Where the committee feels that the charges are such that, in the language of the statute, they "shall deem a trial necessary," these charges may then be referred to a sub-committee of the whole committee, which is

authorized to conduct the hearings and at which the accused doctor will be given a full opportunity to be heard, to produce witnesses and if desired, to be represented by counsel. At this hearing full latitude is given as the law declares that the committee "shall not be bound by the laws of evidence in the conduct of its proceedings." But this does not mean that the committee can find against a doctor unless there is clear legal evidence of guilt, as the statute expressly declares that its determination "*shall be founded upon sufficient legal evidence*."

When the report of the sub-committee is furnished to the whole committee, the whole committee then has power to act upon the recommendation of the sub-committee and it may then, if it desires, take additional evidence. If the committee then decides that the charges are not sustained, they end right there. That terminates the whole matter. In such a case the committee "shall order a dismissal of the charges and the exoneration of the accused." Additional power is given by the statute in these words: "The said committee shall have power, where a proceeding has been dismissed, either on the merits or otherwise, to relieve the accused from any possible odium that may attach by reason of the making of charges against him, by such public exoneration as it shall see fit to make *if requested by the accused so to do*."

But even if the committee finds that the charges are sustained, the committee itself does not possess the power to revoke a license. This power resides in the Regents. The power of the committee is limited to the making of a recommendation to the Regents. But no recommendation of guilt can be made by the committee to the Regents except by a "unanimous vote." When such a recommendation is made to the Regents, the Regents then still have the power of revision as the statute expressly provides that "the Regents after due hearing shall in their discretion execute an order *accepting or modifying* such determination of said committee."

But in any case, where a recommendation of guilt has been made by the Grievance Committee and has been approved by the Regents, the accused has a further opportunity to be heard. In such a case the law provides that he may have "an order of certiorari for the purpose of reviewing such determination returnable before the Appellate Division of the Third Judicial Department." He has a right to apply for a stay of the judgment revoking or suspending his registration or reprimanding or disciplining him "upon application to such Appellate Division after notice to the attorney-general."

In addition to the disciplinary powers possessed by the Committee on Grievances it has certain powers of arbitration. These pow-

ers will be the subject of discussion in our next editorial

The writer, as a member of four bar associations, including the Association of the Bar of the City of New York, believes that he can express a competent opinion that no honorable practitioner of law would at this date consent to the abolition of the grievance committees provided for the governing of the legal profession. Every lawyer realizes that these committees are as much of a protection to him as they are to the public. If he is carrying on his practice honorably, he may enjoy all the security which comes from the consciousness

that unjust or unfounded charges will be summarily dismissed. As the medical profession becomes more accustomed to the idea, it is believed that every doctor will entertain the same feeling of respect and confidence towards the Committee on Grievances as has long been entertained by the lawyers.

Let us, therefore, accord to the Committee on Grievances all the cooperation, confidence and respect to which it is justly entitled. Let us appreciate that what it is doing and trying to do is not against, but for, the medical profession.

### FRACTURED FEMUR—SLIGHT OVERRIDING—CALLUS FORMATION —SUBSEQUENT OPEN OPERATION AND LANE PLATING

A boy of about thirteen years of age was run over by an automobile and his right thigh fractured. Through his guardian he charged the hospital in which he was a patient, and the surgeon who attended him, with negligence in the care and treatment of his injury and sought to recover damages for their alleged negligence. The accident occurred on the 7th of May and he was taken to the hospital in an ambulance.

In the complaint it was charged that the hospital had failed to perform its duty to him in that it had not furnished him with competent and skillful physicians and surgeons or the proper instruments and implements for the care and treatment of his injury and had permitted the surgeons, physicians and nurses to neglect their duties toward the plaintiff, that the defendant physician was negligent, careless and unskilled in his treatment of the injury in that the fracture of the right femur was permitted to remain in the same condition as when the boy first submitted himself for treatment, that a plaster cast was permitted to be placed upon the leg without first properly uniting the fractured bone and the patient was thereby subjected to extreme and unnecessary torture in and about the fractured leg and that the ununited bones were permitted to remain in the plaster cast for a long period of time, so that it became necessary to procure the services of a competent and skillful surgeon to operate upon the boy and properly reduce the fracture, that the negligent and improper treatment of the defendant physician caused a two-inch shortening of the patient's leg. It was claimed that the patient had permanently lost the proper use of his leg and had suffered great bodily and mental anguish, for all of which he asked damages from the defendant physician and the hospital.

Upon entry into the hospital the boy came under the care of the defendant physician, a surgeon of skill and experience in the treatment

of conditions of this nature. At the time of entry into the hospital the patient was in pain, the pain being referred to the region of the right hip and an angular deformity was noticed in the upper part of the thigh. He was carried into the hospital on a stretcher, not being acutely ill but in pain, his lower extremity being in a temporary splint. A general examination made at that time was negative except for the right lower extremity, where there was found fullness in the upper part of the right thigh, with angular deformities outward. On this day, using a Hawley table, the fracture was reduced, the leg placed in Hodgens splints with a Balkan frame, using ten pounds in extension and ten pounds in counter-extension. Three days later three additional pounds were applied to extension. On May 12th an X-ray was taken and the interpretation of the X-ray was "Radiographic examination of right thigh reveals a transverse fracture of the shaft of the femur at the juncture of its upper and middle third. The upper fragment is displaced anteriorly and slightly inward. There is overriding of about one-half inch." The patient complained of burning around the ankle. The adhesive plaster was cut on the posterior surface and a superficial necrosis was found, which was treated with the proper medication. On May 19th the adhesive tape was readjusted. On May 23rd the Hodgens Splints were removed and a plaster cast applied by the defendant physician. On the following day the patient complained of the cast cutting his side and the defendant physician then padded the same with cotton. On May 26th he complained of pain in the ankle which, upon examination, was found to be swollen. Under proper care and treatment the edema of the ankle had subsided and entirely disappeared by June 4th. There was a slight ulceration, however, in the area of Achilles tendon.

The patient continued to get well, there being

no complaints of pain or swelling and on June 18th the cast was removed, at which time the union at the site of fracture appeared complete with some excess callus formation. The boy was then permitted to be out of bed and in a wheel chair. Five days thereafter, against the advice of the defendant physician and the hospital authorities, the boy was removed from the hospital. The parents signed a release which stated the fracture was united with excessive callus formation, the position of both axes good, that there was a slight overriding which would be compensated without deformity, that at his age deformity would disappear. This was the last time the boy received any treatment at the defendant hospital or was seen or attended by the defendant physician.

An action was brought against the parents by a physician who had attended the boy subsequent to his release from the defendant hospital, to recover for his services. In the course of the testimony in this action this physician testified that on June 24th (which was the next day after the boy's removal from the defendant hospital), he took an X-ray of the boy's right leg, which he stated showed a fracture of the femur and the position of the ends of the bone at the time, that the ends of the bone were not touching but were overlapping and that there was some callus union. He also testified that in the following September he took another X-ray of the boy's right leg and the X-ray taken at that time showed the femur, after an operation, with the ends of the bone in contact with the application of a plate to hold the ends together. It was ascertained that within a few weeks after the boy had left the defendant hospital, he entered another hospital, under the care of another surgeon, who performed an open operation which consisted of the breaking up of the callus and refracturing of the femur and the insertion of a Lane Plate and the

application of a Spica cast, that the boy remained in the hospital for about ten days after this operation and was then sent home, that about two months thereafter he returned to the office of the surgeon performing the open operation and the cast was removed, that the ends of the bone had grown together nicely, that the boy had very little shortening, if any, and walked without any signs of lameness. The Lane plating at this time had not been removed.

When this action came on for trial the plaintiff, by his witnesses, sought to establish negligence upon the part of the defendant surgeon in his reduction and treatment of the fracture. The plaintiff, in the trial of the action, sought by the physician who had taken the X-rays subsequent to the boy's leaving the defendant hospital and by the testimony of a physician who claimed that he was not an expert and then proceeded to give expert testimony, that the treatment rendered by the defendant surgeon was not in accordance with the proper and approved practice. The plaintiff also called as a witness the surgeon who had performed the open operation and sought to have this surgeon testify as an expert in behalf of the plaintiff. Under cross-examination this surgeon gave expert testimony supporting and approving the treatment and procedure of the defendant surgeon and that the result obtained by the defendant surgeon was a good result and was not due to any carelessness or negligence on the part of the defendant surgeon and that he performed the open operation and Lane plating only because of the insistence of the parents.

Upon the completion of all the testimony the case was submitted to the jury who, after several hours of deliberation, returned a verdict in favor of the defendant. The result of the trial of this action, which consumed three days, vindicated and justified the treatment of the defendants.

# NEWS NOTES

## CORTLAND COUNTY MEDICAL SOCIETY

At the December meeting of the Cortland County Medical Society the following officers were elected to serve the society during 1927: President, Dr James Walsh, Cortland, Vice-president, Dr Harold E Andrews, Homer, Secretary, Dr Albert A Bailey, Cortland, Treasurer, Dr B R Parsons, Cortland, Delegate to State Society, Dr R P Higgins, Cortland, Alternate Delegate, Dr D R Reilly, Cortland, Board of Censors, Drs B R Parsons, C D VerNooy, F F Sornberger, R P Higgins and D R Reilly, all of Cortland.

This meeting, as decided in the September meeting, took the form of a dinner to our older members, and was held at the Cortland House on the evening of December 15, 1926. Dr Reilly, acting as toast master, introduced Dr Walsh who made some remarks about the medical history of the county and the men who had most to do in making such history, and then addressed himself to Dr H T Dana, our dean, on physicians in the county, and in well chosen words presented to Dr Dana in the name of his fellows of the Cortland County Medical Society a meerschaum pipe. Dr Dana, always graceful in every situation, responded

with a fitting acknowledgement of the presentation, reminded the members that they were remembering his weakness as well as his virtues, and made interesting historical remarks.

Dr Fisher, president of the state society, spoke of medical activities in the state, the new practice act, grievance committee, anti-diphtheria campaign, and mentioned that of all the thousands of dollars which had been appropriated for the immunization of children against diphtheria, none of it went to the physician who administered the toxin-antitoxin, and that while everyone else who touched the work anywhere from the manufacture to the administration, got his or her pay, the physician alone gave his time gratis for the good of humanity.

Dr Fish, of Ithaca, made brief remarks about the affairs of the district branch of the state society of which he is president.

Dr Coville, of Ithaca, told some stories and spoke of the early history of this part of the state.

Dr Frederick Maherty, of Syracuse, spoke about the grievance committee which was recently created and which he said was already in action.

## NIAGARA COUNTY MEDICAL SOCIETY

The annual meeting of the Medical Society of the County of Niagara was held at the Niagara County Sanatorium, Lockport, N Y, on the evening of November 9th, with Dr H U Cramer of Lockport, president of the society, presiding.

The following annual report of the secretary and treasurer was read and accepted.

At the close of the year 1926 the Medical Society of the County of Niagara has eighty-four in good standing, which is a loss of three members over last year. We have lost three members by failure to pay their dues. Each of these men have received three notices since their annual bill was sent to them. We have lost one member by transfer, Dr Jennie E Mabee, who was transferred to the County of New York. We have also lost one member by death. Dr Jesse R. Harris.

We have gained three members by application. Dr Peter J Sciarrino, Dr Ernest M Rieger and Dr Joseph P La Duca, all of Niagara Falls. The Secretary has in his possession, to present to the Censors, the applications of Dr Forest Wm Barry of Lockport, Dr Frederick N G Jerauld and Dr Joseph V Farruggia of Niagara Falls. We have gained one member by transfer, Dr Anne Vele of La Salle, transferred from Erie County.

The treasurer has collected \$1,664 85 and has dispersed \$1,395 47 leaving a balance of \$269 38. There are \$57 50 worth of bills unpaid, leaving a net balance of \$211 88, which is a gain over last year of \$13 88.

We have had five meetings during the year and have been addressed by Drs MacDonald of St Catherine's, Dr Simpson of Buffalo, Dr N G Russell, of Buffalo, Dr Oscar Baer of Niagara Falls, Dr Gordon Heyd of New York, and Dr O'Gorman of Buffalo.

Among State movements, we have endorsed the anti-diphtheria campaign, we have united with Erie for a post-graduate course in pediatrics, and we have sent out large volumes of letters in State Bills before the legislature.

We have obtained the State Meeting for 1927 for Niagara County which meeting is to be held at Niagara Falls, April or May, 1927.

Your Secretary has attended the State Conference of Secretaries held at Albany in September.

The censors reported favorably upon the application of Drs Barry, Farruggia and Jerauld, and they were declared elected to full membership in the Society.

The Secretary reported the transfer of Dr Mabee to the County of New York.

President Cramer reported that the joint post-

graduate courses to be held by Erie and Niagara counties would start November 30 and would last for four weeks. Full information will be sent to the members as soon as the program has been received.

All bills were ordered paid.

Dr Preisch reported for the Committee appointed to investigate the A M A's report on Medical Relief in Disaster. The Committee reported favorably upon the plan as outlined by the A M A and advised that the plan be adopted.

It was moved that the report be recorded and that the Committee be discharged with thanks. Carried.

It was moved that the A M A plan for medical relief in disaster be adopted. Carried.

It was moved that the chair appoint a nominating committee. Carried. Drs Leo-Wolf, Preisch and Scott were appointed.

Dr Schnell reported upon the progress of the work of the committee on arrangements for the State meeting in the spring.

The nominating committee reported the following nominations:

For president, Dr Frederick Leighton, vice-president, Dr Reuben W Shelley, secretary and treasurer, Dr George L Miller, delegates, Dr Frank Guillemont, Dr Frederick J Schnell, censors, Dr Cramer, Dr Crosby and Dr FitzGerald. These were unanimously elected.

Dr Cramer now introduced Dr R W Shelley, Superintendent of the Niagara County Tuberculosis Sanatorium, who presented a most interesting paper upon the subject of "Tuberculosis", and also showed a large number of X-ray pictures. An unusually free discussion followed the paper, being led by Drs Cramer, Leighton, Guillemont and Leo-Wolf, and entered into by most of the members present.

Dr Leo-Wolf moved a vote of thanks to the retiring officers for their excellent service to their society. Seconded and carried.

The meeting then adjourned to a lunch presided over by Dr Shelley in the Sanatorium dining room.

---

## MONROE COUNTY MEDICAL SOCIETY

At the annual meeting of the Medical Society of the County of Monroe, held on December 21, 1926, and marked by exceptional attendance, an unusually impressive memorial tribute was rendered the late Dr Owen E Jones. The picture of Dr Jones was shown on the screen, followed by the reading of this memorial.

"By the death of Dr Owen E Jones the Medical Society of the County of Monroe loses one of its most distinguished members and the City of Rochester one of its most useful public servants.

"Dr Jones was, in the best sense of the word, a servant of his sick, always ready to aid them in their affliction at any time of the day or night, with no thought of the cost to himself in loss of sleep, hardship, or fatigue. Had he not spent himself so freely, he would be among us still. In a profession that has a rightful claim to a reputation for self-sacrifice, he was pre-eminent for the constant forgetfulness of his own comfort and ease in the effort to relieve the disease of his patients.

"He was a surgeon of unusual courage, resourcefulness and skill, instant in decision, wise in council, untiring in the warfare against human ills.

"He gave unstintingly of his time and of himself in furthering the larger interests of the members of his profession, and when his devotion to those interests won for him the highest office in the Medical Society of the State, his unceasing activity and the conspicuous ability which he brought to the task won for him the gratitude and respect of the entire profession.

"He was by nature genial, kindly, friendly and steadfast. We shall not soon look upon his like again, but his memory is of good report among us and will stand for years to come as an inspiration to high endeavor."

During the display of the picture and the reading of the memorial, all present observed a period of silence as a tribute to the former President of County and State Societies and ever-active worker in the Society's affairs.

After routine business, annual reports of standing committees, etc, the Society elected officers for 1927 as follows:

President, Dr Warren Wooden, Vice-President, Dr Cyril Sumner, Secretary, Dr J P Henry, Treasurer, Dr W H Veeder, Censors, Drs E H Howard, F S Winslow, J M Flynn, A S Miller and A G Morris, Milk Commission (for three years), Dr H H Covell and Dr A D Kaiser, Delegates (for two years), Drs C R Barber and J P Brady, Alternates (for two years), Drs J R. Booth and J R Mayer.

The following were elected to membership: Drs F R. Daniels, C B Hert, Margaret M Loder, C H Peachey and J W Thompson.

The scientific program consisted of an extremely interesting and practical symposium on syphilis, presented by members of the society. The first paper, by Dr Edward Gibbs of the Rochester State Hospital, treated of "Recent Advances in Diagnosis and Treatment of Neurosyphilis." Dr Gibbs emphasized the importance of early diagnosis and intensive treatment and

dwelt at length on the recent treatment of par-  
 asis by tryparsamine and the artificial induction  
 of malaria. He took up in detail the tryparsa-  
 mine method as employed at the Rochester State  
 Hospital and exemplified his remarks by present-  
 ing a patient with his case record.

Dr B J Slater spoke on "Syphilis in Industry".  
 He gave a brief but forceful presentation of the  
 important bearing of syphilis on compensation  
 problems and pointed out how treatment worked  
 out to the benefit of the employee, employer, and  
 public health.

Dr Franklin Plumley presented "Clinical  
 Observations on Syphilis," stressing the ne-  
 cessity for extreme care and accuracy in diag-  
 nosis, with intensive and prolonged treatment,  
 succeeded by intelligent and long-continued ob-  
 servation and follow-up.

Following the scientific program, Dr Audley  
 D Stewart, who has recently returned from a  
 hunting trip through British East Africa, enter-  
 tained the society with an exhibition of motion  
 pictures taken on his trip which, to phrase it  
 mildly, proved interesting and exciting.

### BRONX COUNTY MEDICAL SOCIETY

The annual meeting of the Bronx County  
 Medical Society, held at Concourse Plaza, on  
 December 15, 1926, was called to order at 9  
 P M, with the President, Dr Cunniffe, in the  
 chair.

Annual reports for the year 1926 were sub-  
 mitted as follows:

- 1 Report of the Treasurer, Dr J A Keller
- 2 Reports of the Secretary, Dr I J Lands-  
 man, and the Comitia Minora
- 3 Report of the Board of Censors, Dr S  
 M Jacobs, Chairman
- 4 Report of the Counsel, Mr J Clifford  
 McChristie
- 5 Committee on Membership, Dr M R  
 Bookman, Chairman.
- 6 Committee on Public Health and Medical  
 Education, Dr Louis A Friedman, Chairman
- 7 Committee on Medical Economics, Dr  
 Nicholas Lukin, Chairman
- 8 Committee on Audit, Dr P Y Kamenoff,  
 Chairman
- 9 Milk Commission, Dr William Hinz,  
 Chairman
- 10 Committee on Legislation, Dr Harry  
 Aranow, Chairman
- 11 Committee on Hospitals, Dr I H Gold-  
 berger, Chairman
- 12 Special Committee on New Members, Dr  
 A Rostenberg, Chairman
- 13 Building Committee, Dr S Gitlow, Sec-  
 retary of Committee

In each case, it was moved and carried that  
 the report be accepted with thanks.

Election of candidates being in order, it was  
 moved and carried that the Secretary be instruct-  
 ed to cast one ballot for the following candi-  
 dates for membership:

Drs Abraham I Cohen, Joseph Glanzer, Karl  
 F G Hoffmann, Augustus C Kritz, Sebastian  
 Lang, Julius Lehman, David Mandel, Jacob J  
 Miller, Edward Opin, Jean Bertram Ruhl, Leon-  
 ard Shaftab, Elias Shayness, Maurice Umansky

Election of Officers, Censors and Delegates  
 for the year 1927 being in order, it was moved  
 and carried that the Secretary be instructed to  
 cast one ballot for the candidates named by the  
 Nominating Committee. The following candi-  
 dates were then declared elected:

President, Dr Louis A Friedman, 1st Vice-  
 President, Dr Samuel Gitlow, 2nd Vice-Pres-  
 ident, Dr Harry Aranow, Secretary, Dr I J  
 Landsman, Treasurer, Dr J Adlai Keller,  
 Board of Censors, Drs J Bernard Cohen and  
 Irving Smiley, Delegates, Drs J Lewis Amster,  
 Cornelius J Egan, Vincent S Hayward, Edmund  
 E Specht, Alternates, Drs Milton J Goodfriend,  
 Nathan B Jacobson, Nicholas Lukin, Samuel F  
 Weitzner.

Election of Members of the Nominating Com-  
 mittee was then declared to be in order. The  
 following gentlemen were nominated:

Drs Harry Projector, Sydney Steiner, Harry  
 Shiffman, Martin J Loeb, Joseph H Gettinger,  
 William Lenetska, Michael Rosenbluth, Max Nis-  
 selson, Sidney Weil, Samuel Kulkin, Benjamin  
 Diamond.

It was moved and carried that the Secretary  
 be instructed to cast one ballot for the candi-  
 dates named.

Under New Business, the following Resolu-  
 tions were introduced:

"Whereas, The Bronx County Medical So-  
 ciety having sustained a severe loss in the death  
 of its honored associate, Trevor C Yates, M D,

"Resolved, That the Bronx County Medical  
 Society record the sense of its loss in the death  
 of Dr Yates and that a minute thereof be placed  
 on the records of the Society and be it

"Further Resolved, That a copy of these Reso-  
 lutions be transmitted to the family of our de-  
 parted member."

It was moved and carried that the above Reso-  
 lutions be approved.

It was moved and carried that a letter of  
 sympathy be sent to Dr Philip Eichler on the  
 loss of his mother.

The program of the evening as follows

1 Demonstration of Pathological Hearts by  
Slides—Dr Nicholas Lukin

2 Talks on Campaign of Active Immuniza-  
tion Against Diphtheria by Use of Toxin Anti-

Toxin—Drs Edward R. Cunniffe and Louis A.  
Friedman

The Demonstration by Dr Lukin was discussed  
by Drs Pardee and J. B. Cohen. Dr Lukin  
closed the discussion.

---

### CLINTON COUNTY MEDICAL SOCIETY

The annual meeting of the Clinton County Medical Society was held November 16, 1926, at Plattsburgh, N. Y. An informal luncheon preceded the meeting.

An informal talk on the subject of postgraduate instruction brought out requests for some subject in internal medicine or fractures. The physicians present reported about 150 immunizations with toxin anti-toxin in private practice since the last meeting in June, 1926.

Dr I. A. Rowison of Plattsburgh was elected to membership in the Society.

The following officers were elected for the ensuing year: President, Dr G. R. Allen, Vice-President, Dr E. S. McDowell, Secretary, Dr Leo Schiff, Treasurer, Dr F. K. Ryan, Censors, Drs W. H. Ladue, R. S. Macdonald and W. H. Everett, Delegate, Dr Leo F. Schuff, Alternate, Dr W. H. Ladue.

The scientific part of the program consisted of a paper by Dr R. S. Macdonald of Plattsburgh, on the subject "Standardization in Cer-

tain Surgical Procedures," dealing principally with the treatment of fractures. This paper was discussed by Dr L. G. Barton of Plattsburgh.

Dr E. S. Welles of Saranac Lake, by invitation, addressed the society on the subject, "Surgery in Pulmonary Tuberculosis," discussing thoracoplasty and several other surgical procedures, with their indications, contra-indications and results. This lecture was illustrated by lantern slides.

Dr Leo F. Schiff, of Plattsburgh, presented a comparison of the results obtained by the Kahn test and those obtained by the Wassermann test on a series of sera, showing 91 per cent of relative agreement between the two tests, and indicating that the Kahn test was less sensitive than the Wassermann in long standing cases under treatment.

On motion the Clinton County Laboratory was requested to continue performing the Kahn test as a regular procedure in the laboratory.

Attendance, 18.

---

### YATES COUNTY MEDICAL SOCIETY

The following account of the dinner of the Yates County Medical Society, held on January 4th, is taken from the *Penn Yan Chronicle* of January 6th:

"Some 40 doctors and their wives attended the annual meeting of the Yates County Medical Society held at the Benham Hotel in Penn Yan Tuesday evening. Officers elected for the coming year were: Dr O. C. Pacuilli, president, Dr Howard Leader, vice-president, and Dr B. S. Strait, secretary and treasurer. Dr John Hatch and Dr G. E. Stevenson were named delegates from the local society to the state meeting which convenes in the spring. Dr C. E. Doubleday, Dr E. C. Foster and Dr G. E. Stevenson were named censors.

"The dinner was held in honor of Dr Byron Bates Havens of Penn Yan who completed last March his 50th year as a practicing physician in Yates county. Dr Havens was one of the first members of the Yates County Medical Society and consequently has seen its growth during its some 40 years of existence.

"Interesting talks were given by Dr William Lyon, who told of his many experiences when practicing in Siam, by Dr A. W. Armstrong of Canandaigua and Dr A. J. Frantz of Seneca Falls. Dr Schuyler Lott, formerly of Bellona and now of Waterloo, a longtime friend of Dr B. B. Havens of this village, and Dr B. S. Strait spoke in praise of the work of the veteran physician."

---

### THE REHABILITATION HOSPITAL

The Managers of the Rehabilitation Institute and General Hospital wish to correct the statement carried in the 1926 Directory that the institution is temporarily closed. It is open as usual

at 328 West 42nd Street, New York, and in April it will move to new and commodious quarters on 43rd Street, between 9th and 10th Avenues.

# THE DAILY PRESS

## NARCOSAN

The daily newspapers of New York City have recently carried accounts of a new drug for the cure of drug addicts that has been tried in the penal institutions on Welfare Island. *The Sun*, of December 14, carried the following announcement:

"Narcotic addicts can be restored to normalcy within about three weeks by the narcosan treatment, it was announced last night by Frederick A. Wallis, Commissioner of Correction, following seven months of experimentation with 366 cases in the correctional hospital on Welfare Island.

"The announcement was not made until today in order that it might appear simultaneously with the technical report on the tests signed by Dr. Alexander Lambert and Dr. Frederick Tilney and appearing in the *New York Medical Journal and Record*."

The wording of the article gives one the impression that the announcement to the newspapers was made deliberately so that the people generally would get the news as soon as the doctors read it,—and even sooner for probably only a minority of physicians are subscribers to the *Medical Journal and Review*.

Since the item first appeared, other articles have come out almost daily telling about the discoverer of the medicine, and how the drug is produced and how it acts. *The Herald Tribune* of December 16 quotes the opinions of several physicians regarding the drug. Dr. Carleton Simon, a leading authority on drug addiction and a Deputy Police Commissioner is quoted by the *New York Herald Tribune* of December 16 as follows:

"When Horovitz, the discoverer, refused to divulge the formula and the exact method for its manufacture," said Dr. Simon, "I declined to lend myself to the exploitation of it. Hundreds of nostrums have been thrown on the market from time to time, but no new scientific cure has ever been presented in an altruistic manner, the only ethical manner the medical profession will recognize. The commercialization of human suffering should be frowned upon by any one with the interest of the public welfare at heart. I understand that the Horovitz article is a patented article."

The attitude of Dr. Simon is confirmed by an editorial in the *Journal of the American Medical Association* for December 18, 1926, page 2097, which reviews the record of Mr. Horovitz, the promoter of narcosan. The editorial says: "Since his arrival on these shores in 1913, Horovitz has been continuously identified with attempts

to promulgate cures for all sorts of disorders by mixtures of lipoids and vegetable substances of the nature of nonspecific proteins. Included in his records are the Horovitz-Beebe 'cure' for cancer, the Merrell proteogens for the cure of practically everything, and more recently 'narcosan,' originally brought out about 1920 under the name of 'lipoidal substances.' Horovitz' present effort to promote 'narcosan' as a cure for narcotic addiction is supported by a clinical investigation by Drs. Alexander Lambert, ex-president of the American Medical Association, and Frederick Tilney, one of the editors of the *Archives of Neurology and Psychiatry*. The paper by these investigators appears in the *New York Medical Journal and Record* for the week of December 17. This paper was rejected by the *Journal of the American Medical Association* because the Council on Pharmacy and Chemistry rejected the product known as 'lipoidal substances' in 1921, because up to the present time the product has not been resubmitted and is apparently still of unestablished composition, and because the clinical investigations are not set forth in such a manner as to indicate even ordinary controls, such as might have been secured by treating an equal number of patients with the nonspecific proteins alone. Furthermore, on their admittance into the hospital, the patients were given a cathartic mixture consisting of seven ingredients, including some of those in the compound vegetable cathartic pill and a few others. Nevertheless, the paper was promptly accepted by the *New York Medical Journal and Record*, and simultaneously with its appearance in that periodical, a complete statement, highly exaggerated, was issued by the North American Newspaper Alliance."

Following the newspaper publicity inquiries for buying the drug came from all over the United States, many of which came to this *Journal*.

Comments on the drug continued to appear in the daily press, but on January 12 the daily papers stated that the use of the drug in the City institutions was ordered stopped by the State Commissioner of Correction. *The New York Herald-Tribune* of January 12th quoted the statement: "The Commissioners were not impressed with the manner of treatment, and were satisfied from the number of returned prisoners that a cure had not been discovered, and had grave doubts as to whether or not the treatment should be permitted to continue."

The Commissioners of Correction referred the matter to Dr. Matthias Nicoll, Jr., Commissioner

of Health, and the report of the Secretary of the Department of Health, Dr E H Marsh, is quoted in the *Herald-Tribune* of January 12, as follows "Is narcosan a cure? This can be answered only in the negative. The warden in the Workhouse and the three physicians in attendance without hesitation admitted this fact to me. Fifteen persons who had received narcosan treatment have since been recommitted suffering with the drug habit.

"Is narcosan a more humane method of taking addicts off their drugs than any other method? To my mind this must be answered negatively.

"I questioned carefully every person (thirteen) now taking the treatment in the workhouse. All but two of these had had other methods of treatment previously, three or four times, while one confessed to nine previous cures. Every one of these individuals stated that the suffering under narcosan was far worse than with any other treatment. Several stated it was just the same as 'cold turkey' so far as suffering was concerned, but that it made them weaker.

"To satisfy myself that the suffering was more intense and that the physical condition of the patients was worse than in cases of those undergoing rapid reduction (five or six days) treatment, I examined twelve inmates of the penitentiary, half of whom had just been taken off their drugs and half of whom were in various stages of reduction. Not one of these patients was apparently suffering to the extent of the narcosan patients and all were in so much better physical condition that there was no comparison.

"Apparently the narcosan treatment is nothing more than 'cold turkey' plus the administration of a drug, and a regimen which so weakens the patient physically that group control is facilitated. Certainly the statements in the press that narcosan is a 'cure' are wholly unwarranted and should be unhesitatingly condemned.

"However, I do not wish to be unfair. My investigation covered a matter of hours only and further experimentation may show that narcosan has some value as a therapeutic in taking addicts off their drugs, but if this be done it should be carried out under different conditions than those obtaining in the workhouse."

In order to understand what the newspaper comments are about, one needs to consider the article in the *Medical Journal and Record* of December 15, 1926. A reading of that article leaves an impression of vagueness.

The article states "The patent papers show that narcosan is a solution of lipoids, together with nonspecific proteins and water soluble vitamins. The lipoids are obtained from soy beans and cotton seeds by extraction with hot alcohol, the vitamins from plant seeds by percolation with saline solutions, the non-specific proteins from alfalfa seeds or Hungarian millet, by ex-

traction with highly diluted hydrochloric acid. Equal parts of these three solutions are mixed together to form narcosan.

The theory of action of narcosan in the body is that narcotics, such as morphine, call forth in the body certain protective substances to neutralize them. If the narcotic be suddenly withdrawn, and not given, these neutralizing substances are themselves toxic to the body. The lipoids in narcosan neutralize these toxic substances in place of the narcotic.

"After seventy-two hours, because the withdrawal symptoms are over, these neutralizing reactions have ceased, the lipoids are then continued to replace the depleted lipoids in the body. The nonspecific proteins of the narcosan solution are added to stimulate the blood-forming tissues. This is a theory which scientific investigations must prove or disprove."

The account goes on to say that Commissioner Wallis was "anxious to try narcosan as an effective and useful treatment." Special facilities were set aside in the Correction Hospital on Welfare Island and treatment was begun on March 30, 1926.

The account then continues in a general way and says that "some" 219 men and 147 women have been given this treatment. A strong cathartic is first given, and then hypodermic injections of doses of 1 c.c. of narcosan in progressively diminishing intervals over a period of ten days. No detailed history of any case is given, but only a general picture of a typical case. No controls for comparison are described, but some metabolism studies are given.

The account is meager and unsatisfying to a physician who wishes to know the truth about the treatment. It is also unsatisfactory to read further. "Narcosan is equally efficacious in the treatment of other narcotics, such as alcohol and veronal."

Some newspapers voice a disappointment that physicians generally do not accept narcosan with enthusiasm. The *New York Sun* of January 17 says editorially:

"The public is rather weary of a dispute which has not got anywhere. It would like a verdict from competent disinterested men."

The representatives of the State Department of Health and of the American Medical Association, who have investigated narcosan, are both competent and disinterested. The newspapers would doubtless have accepted their statements without question, if the story had not been given to the lay newspapers at the same time that it was published in the medical journals. The original mistake was that of the promoters of the alleged cure in giving statements to the lay press. Editorial comment will be found on page 129 of this Journal.

## THE SPIRIT WORLD

The New York *Herald Tribune* of December 14 comments editorially on a charge made at a conference on spiritualism at Clark University that scientists are hostile to spiritualistic investigations. The editorial says:

"This seems to us a charge utterly without foundation. Far from having ignored the claims of mediums and of supernormalists in general, science has been, if anything, too hospitable to their contentions. It is quite true that the majority of scientific men entertain the conviction that the whole field of spiritualism is based on fraud and fakery, but this conviction is the result of experience, often bitter experience, not of any prejudice or lack of an open mind. We are not aware that any medium of distinction has lacked a scientific audience or has been unable to obtain a committee of distinguished scientific men to witness—and usually to expose—the alleged phenomena.

"Scientific opinion is crystallizing upon the conviction that the so-called 'test conditions' commonly demanded by the mediums render any real scientific investigation impossible. It is urged by spiritualistic advocates that the darkness, the presence of a majority of persons 'friendly' to the medium, and so on, are essential conditions of success. Without them the mysterious 'power' will not operate.

"Possibly these 'conditions' required by the psychics may be necessary ones, but the scientists ask to be allowed to find this out for themselves. Until some medium is willing to place himself or herself unreservedly in the hands of the scientists, even to the risk of life or limb, which the scientists themselves are accustomed to face daily in their own experiments, the majority of the scientific

fraternity may be excused for refraining from excitement about psychic research."

Our knowledge of any phenomenon, physical or spiritual, is gained only by means of our five senses, and all evidence regarding the spirit world must record itself in a physical way on those senses. Tappings, table movements, ghostly appearances, and all other phenomena connected with seances depend on their effect on the senses for proof.

The five senses are crude, and our interpretation of their impressions is still more so. The ear records only a brief range of air vibrations as sound, and the eye only a brief span of the infinite scale of the vibrations of light. Man has the crude suggestions of the existence of other senses besides the five that are ordinarily listed. There is the sense of direction that is well developed in a few persons, but in none does it exist to the degree that it does in carrier pigeons.

The theory of spiritualists is that a medium has a special sensitiveness to impressions from the spirit world whose manifestations take the form of rappings and movements of tables and ghostly appearances. But these evidences are so coarse and crude that they do not lend themselves to accurate measurement.

Our knowledge of constitution of invisible atoms has been based on the discovery of means for recording their phenomena on the five senses. If the phenomena of the spirit world is to affect the senses as clearly and unmistakably as those of the atoms, the means for their detection must be even more accurate and delicate than those used in the investigation of light.

## PARALYSIS OF WILD DUCKS

We usually think that wild animals are strong and healthy, and are not subject to ills and plagues. The truth is that all forms of life are subject to diseases, many of which are as well known as those affecting mankind.

The New York *Herald Tribune* of December 8 contains an article entitled "Duck Paralysis Threatens Wild Fowl of West." The article says:

"'Duck sickness' is chiefly prevalent in the Bear River marshes adjacent to Utah's Great Salt Lake. The sickness causes a paralysis, which, unless the birds are put in fresh water, causes their death. Taken to fresh water in time, the birds are cured.

"In years when duck sickness is least prevalent, the estimated loss is from 30,000 to 100,000 and in the worst years the ducks killed number one and two million, according to an

estimate of David H. Masden, State Fish and Game Commissioner of Utah.

"The 'duck sickness,' he pointed out, not only affects ducks, but all other marsh birds, although the latter are affected to a minor degree. Bear River marshes and the environs are the main feeding grounds for all migratory birds of the Middle West, and, hence, every state in the West to which the birds migrate is affected."

Those who observe birds closely will always find sick individuals. If a flock of meadow larks is fed regularly while the ground is covered with snow, a flock will stay around the feeding spot, and will nearly always contain one or two birds that are evidently sick, and that will soon be found dead. The observed mortality among bird life is great, and is due mostly to infectious diseases. Man is probably more free from infectious diseases than any other animal.

# BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

**WELFARE PROBLEMS IN NEW YORK CITY** Which Have Been Studied and Reported Upon During the Period from 1915 through 1925 By SHELBY M. HARRISON and ALLEN EATON Octavo of 84 pages New York, Welfare Council of New York City, 1926 Paper, 50 cents

**ADVISING THE TUBERCULOUS ABOUT EMPLOYMENT** By W I HAMILTON and T B KIDNER 12mo of 171 pages Baltimore, The Williams & Wilkins Company, 1926 Cloth, \$2.00

**BIOLOGICAL RELATIONS OF OPTICALLY ISOMERIC SUBSTANCES** By ARTHUR R. CUSHNY, M.A., M.D. Octavo of 80 pages Baltimore, The Williams & Wilkins Company, 1926 Cloth, \$2.00 (The Johns Hopkins University, School of Medicine, The Charles E. Dohme Memorial Lectures, Third Course, 1925)

**PRINCIPLES AND PRACTICE OF CHEMOTHERAPY** With Special Reference to the Specific and General Treatment of Syphilis By JOHN A. KOLMER, M.D. Octavo of 1,106 pages, with 82 illustrations Philadelphia and London, W B Saunders Company, [1926] Cloth, \$12.00

**ANATOMY OF THE WOOD RAT** Comparative Anatomy of the Subgenera of the American Wood Rat (Genus Neotoma) By A. BRAZIER HOWELL. 8vo of 225 pages, illustrated Baltimore, The Williams and Wilkins Company, 1926 Cloth, \$5.00 (Monographs of the American Society of Mammalogists, Number One.)

**GENIUS** Some Revaluations By ARTHUR C. JACOBSON M.D. Octavo of 160 pages. New York (Adelphi Company), Greenberg, [1926] Cloth, \$2.50

**LABORATORY OUTLINES IN BACTERIOLOGY AND IMMUNOLOGY** By JOHN F. NORTON, Ph.D., and I S. FALK, Ph.D. Octavo of 114 pages Chicago, Illinois, The University of Chicago Press, [1926] Cloth, \$2.00

**THE MEANING OF DISEASE.** An Inquiry in the Field of Medical Philosophy By WILLIAM A. WHITE, A.M., M.D. 12mo of 220 pages Baltimore, The Williams and Wilkins Company, 1926 Cloth, \$3.00

**THE NATURAL INCREASE OF MANKIND** By J. SHIRLEY SWEENEY, M.A., M.D. Octavo of 185 pages Baltimore, The Williams and Wilkins Company, 1926 Cloth, \$4.00

**MILITARY MEAT AND DAIRY HYGIENE.** Prepared Under the Direction of the Surgeon General of the United States Army Compiled by CAPTAIN HORACE S. EAKINS, V.C. Octavo of 647 pages Baltimore, The Williams and Wilkins Company, 1924 Cloth, \$6.50

**CLINICAL SURGICAL DIAGNOSIS FOR STUDENTS AND PRACTITIONERS** By F. DEQUERVAIN Translated by J. SNOWMAN, M.D. Fourth English Edition. Octavo of 937 pages, with 750 illustrations and 7 plates New York, William Wood and Company, 1926 Cloth, \$14.00

**THE REPRODUCTION OF LIFE.** A Handbook of the Science of Reproduction in Nature and Man By A. J. COKKINIS, F.R.C.S. 12mo of 287 pages, illustrated New York, William Wood and Company, 1926 Cloth, \$3.50

**HUMAN PATHOLOGY** A Textbook By HOWARD T. KARSNER, M.D. With an Introduction by SIMON FLENNER, M.D. Octavo of 980 pages, with 463 illustrations Philadelphia and London, J. B. Lippincott Company, 1926 Cloth, \$10.00

**REMINISCENCES** By GEORGE HENRY FOX, A.M., M.D. Octavo of 248 pages, illustrated New York, Medical Life Press, 1926 Cloth, \$3.50

**A SOUND ECONOMIC BASIS FOR SCHOOLS OF NURSING AND OTHER ADDRESSES** By MARY ADELAIDE NUTTING R.N., M.A. Octavo of 372 pages New York and London, G. P. Putnam's Sons, 1926 Cloth, \$2.50

**MEDICAL RECORD VISITING LIST OR PHYSICIAN'S DIARY FOR 1927** 6½ by 3¾ inches New York, William Wood and Company, 1926 Flexible Leather Prices are for 30 patients per week, \$1.75, for 60, \$2.00, for 90, \$2.50

**THE SCIENTIFIC BASIS OF CHEMOTHERAPY** By IWAN I. OSTROMISLENSKY, Ph.D., M.D. 12mo of 142 pages New York (The Author), 1926 Paper

**THE PRACTICAL MEDICINE SERIES** Comprising Eight Volumes on the Year's Progress in Medicine and Surgery Under the General Editorial Charge of CHARLES L. MIX, A.M., M.D. Series 1926 Chicago, The Year Book Publishers, 1926 General Medicine. Edited by GEORGE H. WEAVER, M.D., LAWRENCE BROWN, M.D., ROBERT B. PREBLE, A.M., M.D., RALPH C. BROWN, B.S., M.D. 12mo of 737 pages, illustrated Cloth, \$3.00 Price of the series of eight volumes, \$15.00

**THE MEDICAL DEPARTMENT OF THE UNITED STATES ARMY IN THE WORLD WAR.** Prepared Under the Direction of MAJOR GENERAL M. W. IRELAND Volume VI Sanitation in the United States, by COL. WESTON P. CHAMBERLAIN, M.C., in the American Expeditionary Forces, by LIEUT.-COL. FRANK W. WEED, M.C. Quarto of 1,141 pages, illustrated. Volume XIV Medical Aspects of Gas Warfare, by COL. WILDER D. BANCROFT, C.W.S., and others Quarto of 876 pages, illustrated. Washington, Government Printing Office, 1926

**CLINICAL APPLICATION OF SUNLIGHT AND ARTIFICIAL RADIATION** Including Their Physiological and Experimental Aspects with Special Reference to Tuberculosis By EDGAR MAYER, M.D. Octavo of 468 pages Baltimore, The Williams and Wilkins Company, 1926 Cloth, \$10.00

**THE MEDICAL CLINICS OF NORTH AMERICA.** Vol. 10 No. 3 November, 1926 (Mayo Clinic number) Published every other month by the W B Saunders Company, Philadelphia and London Per Clinic Year (6 issues) Paper, \$12.00 net, Cloth, \$16.00 net.

**SKETCH OF THE HISTORY OF THE MAYO CLINIC AND THE MAYO FOUNDATION** From the Division of Publications, Mayo Clinic. Octavo of 185 pages Philadelphia and London, W B Saunders Company, 1926 Cloth, \$3.50

# BOOK REVIEWS

**AN ATLAS OF MIDWIFERY** By COMYNS BERKELEY, M A, M C, M D, and GEORGES M DUPUY, M D Octavo of 160 pages with illustrations New York, William Wood and Company, 1926 Cloth, \$3 00

This little book contains a fairly complete set of the illustrations usually found in a text book on obstetrics. There is no text except the legends under the diagrams and drawings. Under episiotomy it is interesting to note that the authors state that this incision is "but rarely employed." A handy book for the medical student—it is simplicity itself. C A. G

**GOULD'S MEDICAL DICTIONARY** Containing All the Words and Phrases Generally Used in Medicine and the Allied Sciences, With Their Proper Pronunciation, Derivation and Definition. By GEORGE M GOULD, A M, M D Edited by R J E. Scott, M D Octavo of 1,398 pages, with illustrations and tables. Philadelphia, P Blakiston's Son and Company, 1926. Flexible leather, \$9 00

Gould's Medical Dictionary has long been a standard, and this revision by Dr Scott brings the volume up to date. The definitions are clear and concise, and the pronunciation and derivations of the terms are given in a satisfactory manner. The book answers all the purposes of a medical dictionary.

FREDERIC DAMRAU

**A PRACTICAL MEDICAL DICTIONARY** By THOMAS LATHROP STEDMAN, A M, M D Ninth edition Octavo of 1178 pages, illustrated. New York, William Wood and Company, 1926 Flexible leather, \$7 50

It is only two years since the eighth edition of Stedman's medical dictionary was published, therefore, extensive changes were not necessary. Several hundred new words have been added, bringing the dictionary up to date, and the names of some of the proprietary preparations no longer advertised have been dropped. Various changes were made to make the text conform to the new editions of the U S Pharmacopoeia and National Formulary and an alphabetical table of drugs and their indications has been added. The plates have been taken from the back of the book and distributed throughout the text.

The ninth edition brings up to date a thoroughly satisfactory medical dictionary. FREDERIC DAMRAU

**PRACTICAL DIETETICS FOR ADULTS AND CHILDREN IN HEALTH AND DISEASE.** By SANFORD BLUM, A. B, M S, M D Second revised edition Octavo of 362 pages. Philadelphia, F A Davis Company, 1926 Cloth, \$4 00

In this book definite, quantitative diets are given only for infant feeding and for typhoid fever. For typhoid fever only two definite diets are given, one, for the first week of the disease, which supplies about 20 grams of protein and 300 calories, and the other, for the second and third weeks, which supplies about 20 grams of protein and 500 calories. These typhoid fever diets differ materially, in quantities at least, from those advocated by many good authorities at the present time. For all the other diseases and conditions mentioned in the book no definite diets are given but only menus (in which are rarely seen references to household measurements) and diet lists labelled "may eat" and "avoid." Those who are satisfied to practice dietotherapy with diet lists and menus may be interested in this book, but to those who understand by a diet, definite articles of food taken in definite quantities, in definite periods of time, the book will hardly appeal. E. E. C

**ESSAYS IN THE HISTORY OF MEDICINE.** By KARL SUDHOFF, M D Translated by various hands and edited, with foreword and biographical sketch, by Fielding H. Garrison, M D Octavo of 397 pages New York, Medical Life Press, 1926 Cloth, \$5 00

The book contains the English translations of thirty eight essays by Professor Sudhoff and is edited by Dr Fielding H Garrison, who also contributes a foreword and a biographical sketch of Professor Sudhoff. Dr Garrison also translates several of the essays.

Among the names of the other translators are Doctors Allemann, Hemmeter, Krumbhaar, Radin, Riesman, Ruhräh, Seelig and Stockman. Also Felix Neumann, of the Surgeon Generals Library, and George Panebaker and Emilie Recht, of the "Medical Life" staff.

A book on the history of medicine by Professor Sudhoff, sponsored by Dr Garrison, needs no recommendation.

The book is well printed and made and moderately priced. I O TRACY

**I BELIEVE IN GOD AND IN EVOLUTION** By WILLIAM W KEEN, M D Fourth Revised Edition, 12mo of 109 pages, illustrated. Philadelphia and London, J B Lippincott Company, 1925 Cloth, \$1.25

11,000 copies of this book have come from the press. The number of copies sold proves the interest of the reading public in this subject. There are a great quantity of books appearing on the subject of evolution. Each one is more or less of a repetition of those previously published, and very few new data are added. This book attempts by its title to reconcile the Bible and Science, but it does not do so, because the author does not believe in accepting the Bible as written. He accepts the early part of it by interpreting it as a bit of oriental picture writing. The Doctor gives a new interpretation of many of the malformations of the human body so as to make them coincide with the theory of evolution. Comparative anatomy has not helped in solving the theory of evolution. It is just as unsolved as it ever was, and will remain so for some years to come.

This is an interesting little book, written by one of America's eminent physicians who has contributed much through a long life. The book deserves the kindly reception it is receiving by the friends and foes of the subject considered. J ARTHUR BUCHANAN

**THERAPEUTICS, MATERIA MEDICA, AND PHARMACY** The Special Therapeutics of Diseases and Symptoms, the Physiological and Therapeutical Actions of Drugs, the Modern Materia Medica, Official and Practical Pharmacy, Prescription Writing, and Antidotal and Antagonistic Treatment of Poisoning. By SAMUEL O L POTTER, A.M, M.D, M.R.C.P, Lond. Fourteenth Edition, revised by R J E SCOTT, B.C.L, M.D Octavo of 672 pages. Philadelphia, P Blakiston's Son and Company, 1926 Cloth, \$8 50

This work, now in its fourteenth edition, is as usual an excellent book, fulfilling the wants of the student and practitioner alike. This edition has been thoroughly revised and conforms to the changes made in the U S P X, giving also a brief description of the non-official drugs and preparations. Here can be found, in a concise form, the physical properties and chemical constituents of drugs, their doses, preparations and incompatibilities. The section on Therapeutics is well constructed and gives at a glance the remedies best suited in the treatment of various conditions.

The book is valuable and highly recommended as an authoritative treatise on the subjects of Therapeutics, Materia Medica, and Pharmacy. FREDERICK SCHROEDER

**AN INTERMEDIATE TEXTBOOK OF PHYSIOLOGICAL CHEMISTRY WITH EXPERIMENTS** By C. J. V. PETTIBONE, Ph.D., Associate Professor Physiological Chemistry, Medical School, University of Minnesota, Minn. Third Edition. The C. V. Mosby Co., St. Louis, 1925. Price \$3.25.

Obviously when a book reaches the third edition its worth is soundly established by that fact alone. Nor is it difficult to understand why this little book has been valued so highly by those who know it.

As its title suggests, it represents an effort to bridge the gap between general chemistry and the more detailed studies of physiological processes.

It does not suffer the limitations of the elementary text book—it is meat from cover to cover—a study in conciseness—and has appended a laboratory outline which presents a carefully selected group of experiments with clear, terse but adequate directions for their performance.

G. H. ROBERTS

**A HANDBOOK FOR SENIOR NURSES AND MIDWIVES** By J. K. WATSON, M.D., 12mo of 554 pages with illustrations. New York, Oxford University Press, 1926. Cloth, \$4.00 (Oxford Medical Publications).

This is the first edition and first printing of this volume and being a small compact book well printed with particularly accurate anatomical illustrations as well as instrument and appliance illustrations, it should be an excellent reference volume for those to whom it is dedicated.

The subjects are well covered in a very readable manner. The chapter on "Prevention of Disease"—a very important subject for the nurses of today, especially those who are doing social hygiene work—is entirely too brief for any practical benefit.

The book would certainly be an excellent handbag companion to any nurse.

HERBERT T. WIKLE.

**THE DIAGNOSIS, TREATMENT AND END RESULTS OF TUBERCULOSIS DISEASE OF THE HIP JOINT** By GEORGE FERRINS, MCH Oxon., F.R.C.S., Eng. Octavo of 118 pages, with illustrations. New York, Oxford University Press, 1926. Cloth, \$1.75 (Oxford Medical Publications).

The writing of specific monographs on disease of selected regions is an excellent custom. It produces a book that is compact, easily handled, popular with students and the subject matter tends to be concise and definite. Of such a character is this book on the hip joint. About thirty pages of the one hundred are devoted to a frank and illuminating discussion of the end results of treatment and in these pages there is much of true value. The author here compares the character of the treatment and the results showing where failure of proper care produced the deformity. The book is published in an excellent manner and fully illustrated.

J. C. R.

**THE PRINCIPLES OF ANATOMIC ILLUSTRATION BEFORE VESALIUS** An Inquiry into the Rationale of Artistic Anatomy. By FIELDING H. GARRISON, A.B., M.D. 12mo of 58 pages with illustrations. New York, Paul B. Hoeber, Inc., 1926. Cloth, \$2.50.

This small book, written by a master, carries an object lesson—the author tries to stimulate the physician to use his power of observation when examining the sick, just as the ancient and mediaeval masters used theirs when conveying upon paper, canvas or in marble their impressions of the body in toto or dissected. Every lover of medical history, and we are quite confident there must be a great many, should possess this gem. It is most interesting reading, but unfortunately not enough. It creates the desire to read on and on. The story and the illustrations are wonderful.

GAETANO DE YOANNA.

**EXPERIMENTAL PHARMACOLOGY AS A BASIS FOR THERAPEUTICS** A Text-Book for Students and Physicians. By DR. HANS H. MEYER and DR. R. GOTTLIEB. Second edition in English translated by VELIEN E. HENDERSON from the Seventh Revised German Edition. Octavo of 656 pages with illustrations. Philadelphia and London, J. B. Lippincott Company, 1926. Cloth, \$7.00.

This is the Seventh German Edition and the Second English translation of this exceedingly interesting book. Some slight changes were made in the German text so as to conform to the scientific names of the drugs of the Tenth Revision of the United States Pharmacopoeia, and likewise the British Pharmacopoeia, 1914, with the pharmacopoeial doses of these books. The usual classification of drugs according to their actions in the body has been departed from and the subject is approached from the physiology of each organ and its pathological condition, endeavoring in this way to show how its function may be altered by the use of certain remedial agents. The sections dealing with the central nervous system, kidney, and metabolism are exceptionally good.

This book is invaluable to all advanced students and teachers of this subject.

FREDERICK SCHROEDER.

**MESENTERIC VASCULAR OCCLUSION** Supplemented by an Appendix of 76 Original Cases. By A. J. COKKINIS, M.B., B.S., F.R.C.S. Octavo of 159 pages. Eng. New York, William Wood and Company, 1926. Cloth, \$4.00.

Mesenteric vascular occlusion is one of the abdominal calamities the surgeon meets with not infrequently. The author, as a result of some personal experiences with a few of these cases, undertook a thorough study of the literature on this subject as well as a complete analysis of a large number of hospital cases. He has also carried out a series of experiments on animals, in order to determine the degree of collateral arterial supply by occluding the main trunks, and then the various branches in the mesentery.

These investigations have led to certain definite conclusions, which will, no doubt, prove of practical help to the surgeon, for the treatment must depend upon a proper understanding of the pathology.

HERMAN SHANN

**A MANUAL OF THE PARASITIC PROTOZOA OF MAN** By CHARLES F. CRAIG, M.D., M.A. Octavo of 569 pages, illustrated. Philadelphia and London, J. B. Lippincott Company, 1926.

This manual is different from any others treating of the parasitic protozoa in that it is written for the practicing physician and not for the student of protozoology. However, the latter will find excellent and complete descriptions of the protozoa, but the author's primary aim has been to make his work of value to those who must diagnose and treat these diseases. His many years of experience and high rank as a protozoologist make him speak with authority.

He describes amebae, flagellates, coccidia, malarial plasmodia, sarcosporidiae and ciliates systematically under morphology, resistance, habitat, cultivation, life-history, distribution, infection and transmission and the disease each produces with symptoms, diagnosis, prevention and treatment. There is a full discussion of the more important protozoan diseases such as amebic dysentery, sleeping sickness, kala-azar and malaria. There are many illustrations picturing the various forms of most of the protozoa described. In spite of its technical nature the author has succeeded in making a very readable book and the reviewer found much of interest.

E. B. SMITH

# OUR NEIGHBORS

## BUSINESS PHILOSOPHY

Every editor is anxious to ascertain the reaction of his readers toward his journal—and the discovery of the truth is often surprisingly difficult. An editor can always find abundant confirmation of his choice of subjects and justification for his policies, for much that he publishes has come to him as the result of conversations and letters and speeches which he has heard. But the organ of a state medical society represents the great majority of the physicians of his state, and most of them do not say what they want, although too frequently they tell their neighbors what they don't want. But after all, physicians are kind and simply ignore the reading matter which does not appeal to them.

Dr Frank C Hammond, the editor of *The Atlantic Medical Journal*, the organ of the Medical Societies of Pennsylvania and Delaware, thinks that doctors would acquire a taste for the matter in all departments of their State Journal if they would read it to discover what it contains. His views are expressed in a brief editorial entitled "Business Philosophy," which reads as follows:

"William Feather states that 'one of the great-

est business geniuses of this country has always made a rule of asking himself regarding every thing he sees, hears, or reads 'How can I use that?' and further, 'How I can use that?' is a query that should be in the minds of all of us as we go about from day to day. Experience is of no value unless we translate it into life itself.' How many of our members read through the *Journal* from cover to cover, and make practical application in their every day work of the many lessons therein learned.

"We have asked a number of our readers to what extent they read the *Journal*. The answers may be summarized as follows. They thumb the *Journal* through and read the editorials or the news items or the ads, and too frequently there it ends, whereas a wealth of material is delivered at their doors regularly every month, if they would but take advantage of it. It is a duty they owe primarily to their patients and secondarily to themselves.

"Establish the habit. Read your State Journal. Read it through and apply in your daily work what you learn therefrom."

## CAMPAIGNS FOR LAWS ON MEDICAL PRACTICE

Suggestions regarding the management of campaigns for the passage of wise medical laws were made by Dr J Allison Hodges of Richmond, Virginia, on October 12, at the annual meeting of the Medical Society of Virginia, and were reported in the December issue of the *Virginia Medical Monthly*. Dr Hodges' plan was that committees of doctors should get in touch with lay organizations as has been done in New York State. Dr Hodges said:

"In this fast-moving age, the individual as a personal entity has been merged largely into the group class, and the facilities for mass education have never been so numerous, nor so effective. Already physicians have accomplished much, individually and through their associations, through medical colleges and state and federal governmental agencies, but the people do not know these things, they do not know even that nearly all of the great discoveries and inventions in the field of scientific therapy 'which have extended the average of human life in the memory of us all over ten years, and which in the future will

extend it another decade by eliminating the epidemics which in the past have swept millions to an undeserved death,' can be traced to the door of the doctor—never to the gilded den of the quack. In the future, the doctor must not be the lone voice crying in the wilderness, he must forego his time-honored reticence."

"It has been claimed by some puny pessimists that since quacks still exist, and have always for that matter, nothing can be done, nor has ever been done, to remedy the evil, but this is idle gossip, due only to the misconception by the doctor of one of the basic duties of his profession, and the consequent ignorance of the public because of the lack of proper knowledge or because of misrepresentation of the true facts by designing irregular practitioners.

"Probably there was never a time when a closer relationship between the doctor and the public was more desirable or more necessary than at present, for the increasing number of specialists, and the decreasing number of country practi-

# Sinus Evacuation

*"Acts by Suction"*

## A Simple, Safe and Scientific Method of Cleansing and Draining the Nasal Cavities at Home

**I**N many conditions arising in and about the nasal cavities routine, periodic drainage, and cleansing of the mucosa of the nose is clearly indicated. It is particularly effective if the mucosa has become irritated due to some infectious process.

The NICHOLS NASAL SYPHON is designed to accomplish this in a safe, simple and practical manner in the hands of the patient at home. It is a simple but ingenious device, utilizing the principle of syphonage as a basis but with nasal attachments and an outlet tube to a basin on the floor, allowing an even flow of solution from one nostril into the naso-pharynx and out the other.

When the attachments are applied to the nostrils a suction action is induced which draws upon the retained mucus not only in the nose but in the sinuses as well.

Properly applied, the syphon accomplishes the cleansing and evacuation easily and quickly.

The relief experienced by the patient makes him willing to use the device as directed by you—and you have the confidence, instilled by the safety and simplicity of the device, that it will aid considerably as an extra office treatment at home in the alleviation of many conditions.

## A New Source of Fresh Cod Liver Supply

*The beam trawler is one of the types of fishing boats that sail from our Atlantic ports*

To supply the constantly increasing demand for Patch's Flavored Cod Liver Oil it has been necessary for us to greatly increase our liver supply by installing many new plants along the Atlantic coast during the past year.

We have also developed a type of cooker which is being successfully operated on the large steam trawlers while they are far out at sea.

As soon as the nets are hauled in, the fish are immediately cleaned. The fresh livers are taken by our men who ship with the crew, directly to the cooker where the oil is extracted at once.

The excellent crude oil thus produced right at the source of the fresh liver supply is taken to our main plant at Gloucester, Mass. Here it is chilled to remove the stearin.

Only by giving close attention to the matter of fresh liver supply can we maintain the high quality of PATCH'S FLAVORED COD LIVER OIL, a sample of which will be mailed to you if you will send us the coupon below.

Taste it! You'll be surprised!!

Dr.

Street & Number

City & State

NY J

tioners, together with the materialistic attitude of some of our unthinking members, have made the gap between physician and patient wider, and to a certain extent undermined the respect in which the medical profession is held. As proof of these facts, it may be stated briefly that, during a sixteen year period of one of our great medical universities, this institution has sent out 965 graduate doctors, and only four of them today are practicing their profession in rural districts, and many, if not most of the others, have entered the field of specialism.

"The case of the mountainous section of Virginia, West Virginia and North Carolina is outstanding, for five million mountaineers, pure-bred Americans, live in isolation in their highland empire, without a single doctor in some of the counties. Granting, then, that a medical necessity exists, and that education, and education alone, of both the physician and the public can meet this situation, and thus unhorse the medical pretender, who is seeking legal recognition, what is the practical solution?"

"As a general plan for preventing and eliminating the conditions named, and as an entering wedge into what must ultimately become universal health education, the following recommendations are submitted:

"The appointment by the State Chairman of the Executive Council of a local Professional Relations Committee, consisting of three physicians resident in each Councilor district, who shall have charge locally, with the State Chairman of the Executive Council and the Chairman of the State Legislative Committee, of all medicolegislative problems that may arise in such districts,

"That these local committees in each Councilor district shall have the right to organize according to their own preferences, and shall have the authority to associate with themselves such local medical, educational, religious, health and lay associations, especially the local Woman's Auxiliary, as they may deem proper, the local chairman keeping the State Councilor Chairman informed, and he in turn, to keep in contact with the State Legislative Chairman in all matters relating to medical legislation.

"The dominant purpose in all this is to develop direct contacts through associated and helpful agencies in the home districts that will educate the law-makers and the public to secure the enactment of constructive legislation designed for the common good. This will be no easy task, but it is not an impossible one, and is one that should appeal, not to the profession as a mere profession, but to the true and loyal spirit of the profession of medicine. Medical legislation is only a means to an end, and the average legislator is ready to listen to an unbiased lay opinion.

ion, consequently, the desire of the physician not to gain a patient, but for the patient to gain health, will be better understood and appreciated."

### SCIENTIFIC SERVICE COMMITTEE

The Illinois State Medical Society is conducting a scientific service for supplying speakers for meetings of County Medical Societies, to which reference was made on page 101 of our last issue. The January number of the Illinois Medical Journal contains further information regarding the findings of the Committee that has the service in charge, and the further development of its plans. The committee had conducted a questionnaire into the choice of subjects for the scientific meetings. The article says:

"From the above return on the questionnaire, we must draw the conclusion that the men prefer clinics and round table discussions, with only a small per cent preferring papers. It is also my opinion that if we can get this form of meeting developed, we can interest all of the local men in taking an enthusiastic part in the meetings. The Committee will stress the clinical aspect wherever possible in presentations before county and district medical societies. This will require co-operation from the society requesting service, but will abundantly repay them for the additional effort."

### COURSES OFFERED *Internal Medicine*

- 1 Peptic Ulcer  
Gastric—duodenal  
Diagnosis—treatment  
Medical—surgical
- 2 Gall Tract Disease  
Diagnosis—prognosis—medical treatment
- 3 Diabetes  
Diagnosis—management
- 4 Respiratory Infections  
Influenza  
The pneumonias  
Common colds
- 5 Cardio-vascular Disease  
Diagnosis and treatment of early heart failure—of advanced heart failure
- 6 The Nature and Significance of Cardiac Murmurs—of Cardiac Pain—of Cardiac Irregularities
- 7 The Prevention of Cardiac Disease
- 8 Kidney Disease  
Simplification of nomenclature and classification, clarifying nephritis and nephrosis  
Diagnosis—treatment
- 9 Gout  
Simple classification

## SALIPYRIN *Riedel*

Is a chemical combination of antipyrin and salicylic acid. The therapeutic effects of both these components are preserved, although modified by close chemical union and in a very great degree deprived of the dangers of mechanical mixtures.

Salipyrin is distinguished from other salicylates

by the comparative freedom from ill-effects (absence of free antipyrin) and prompt antipyretic and sedative action

**INDICATIONS** Influenza, Colds, Catarrh of the Nose and Throat, Rheumatism, Neuralgia, Alcoholic Excess, Pleurisy, Dysmenorrhea, Metrorrhagia Vaginitis, etc. If given early in the attack, Salipyrin generally succeeds in aborting colds

Salipyrin is supplied in powder form and as SALIPYRETS in tablets of  $7\frac{1}{2}$  to 15 grains each.

Approved by the Council on Phar and Chem. of the American Medical Association for inclusion with N N R.

# What is Nonspi?

**N**ONSPI is an antiseptic liquid for Axillary Hyperidrosis which you can recommend to your patients with absolute confidence. It is a preparation which destroys armpit odor by removing the cause—excessive perspiration. This same perspiration, excreted elsewhere through the skin pores, gives no offense, because of better evaporation.

NONSPI has for years been used by innumerable women everywhere and is endorsed by high medical authority in America and Europe.

Physicians, surgeons and nurses find the regular use of NONSPI insures immaculate underarm hygiene and personal comfort, so essential to those who come in contact with the ill and sensitive.

To keep the armpits normally dry and absolutely odorless NONSPI need be applied in the average case, but twice a week.

50c a Bottle, at Toilet and Drug Counters.

## MEDICAL LEGISLATION IN MISSOURI

The Journal of the Missouri State Medical Association for December has an editorial on the medical legislation that may be expected this winter. It says

"In the proposed plan for the abolishing or consolidation of the present 123 boards and commissions now existing, it is intended to legislate them all into ten divisions. The State Health Department will be one of the units taking the place of the board of health. The principal officer will be the secretary. There will be an advisory board composed of seven physicians. The Department of Health will have divisions for vital statistics, sanitation, child hygiene, a bacteriological division, and will supervise all investigations of social diseases as well as the work for the prevention of blindness. The Pure Food and Drug Department of the state government will be merged with the Department of Health. Under the consolidation idea, a feature that may occasion much discussion is the examination of medical students. A Department of Education and Registration is to be created. A director of education, to be appointed by the Governor, with a board of regents composed of seven members will conduct all examinations, medical or otherwise, where the law requires a state license.

"The proposed amendments to the medical practice act, to be submitted to the General Assembly by the Missouri State Medical Association, should meet with the approbation of the layman. Much has been written about the diploma mills where ignorant, irresponsible, untruthful and inexperienced men have purchased their diplomas from dishonest educators. The sick need real medical advice. This only should be given by men who can diagnose the ailments through experience obtained from medical training at reputable medical colleges. The featured amendments to be presented by the State Medical Association will enact a section requiring applicants for licenses to practice medicine in Missouri to have attended at least four terms of nine months each and to have received a diploma from some reputable medical college.

# INTESTINAL INFLUENZA

An editorial in the January issue of *Northwest Medicine*, the organ of the Medical Societies of Oregon, Washington and Idaho, calls attention to the unsatisfactory nature of a diagnosis of intestinal influenza—a diagnosis which is sometimes made in the Empire State. The editorial is as follows:

"A generation or more ago the term 'malaria' was a safe refuge for the diagnostician who was unable to determine the true nature of febrile conditions. It was in general use for that purpose until the discovery of the plasmodium malariae, after which there was no excuse for this diagnosis on the part of any physician, unless the patient was truly infected with malaria. At the present time the diagnosis 'intestinal flu' is analogous to the former use of malaria. Its introduction dates from the influenza epidemic of 1918, since which time it has been widely and loosely employed as a cloak for ignorance in a variety of abdominal disorders. For many years 'ptomaine poisoning' was the popular designation for uncertain and obscure intestinal disorders. At present, however, that seems to have been largely retired in favor of the diagnostic label under consideration.

"Whether intestinal influenza is an entity which really exists is a matter of dispute. In no authoritative textbook is it listed as a distinct ailment. Tice states that gastrointestinal complaints are present at times during attacks of influenza, the symptoms of which are purely functional in character. While occasionally accompanied by bloody discharge and stringy mucus, these are the only evidence that at times the disease develops definite signs of catarrhal, inflammatory or ulcerated conditions. Stevens affirms that gastrointestinal symptoms were not uncommon in the epidemic of 1889, but comparatively rare in that of 1918. Intestinal symptoms of abdominal pain, nausea, vomiting and diarrhea are occasionally sufficiently severe to suggest cholera morbus or dysentery. Sajous mentions similar circumstances in the digestive tract as a complication at times of influenza. Abt claims that the gastrointestinal type of influenza occurs mainly in children and young adults. In some cases, he states, there may be no signs referable to the respiratory tract, though children thus affected often complain of abdominal symptoms. The writer on this subject in Osler and McCrae's *Modern Medicine* declares that this form of influenza as an entity is of uncertain existence. He has never seen a case with absence of respiratory symptoms in which the diagnosis was sure.

"Thus, it is to be noted, the opinion seems to prevail that the intestinal tract may be affected by the organism producing influenza, most commonly, however, as a complication of this recog-

nized disease. In this discussion the protest is against the off-hand and easy diagnosis of 'intestinal flu' in the presence of a variety of indefinite abdominal symptoms. For the purpose of accuracy the conscientious physician will, so far as possible, make his diagnosis in accordance with established pathology and symptomatology. In the absence of these factors let him admit his inability to arrive at a satisfactory diagnosis. It harms neither patient nor practitioner for the latter at times to admit he does not know, although such admission is most difficult on the part of many physicians."

## A BROAD-MINDED JUDGE

A news item in the December issue of the *Journal of the Missouri State Medical Association* describes the action of a Judge in Kansas City in dismissing a suit brought against the city health officer for ignoring the Judge's order restraining the commissioner from proceeding against a certain unsanitary dairy. The item reads:

"A suit against Dr. E. W. Cavaness, city health director of Kansas City, and O. C. Murphy, food and dairy commissioner, for contempt of court was dismissed by Judge Coon, November 20. Judge Coon had issued a restraining order prohibiting the city authorities from interfering with the dairy activities of L. K. Hebel, charged with selling milk contaminated from a polluted spring on his dairy farm, thus causing the milk to become a source of typhoid fever. In spite of the restraining order, the health director and the food and dairy commissioner sought to prevent the sale of milk from Hebel's dairy. In declining to issue a citation of contempt against the city officials, Judge Coon said: 'If the defendants had good reason to believe that the milk being sold by Hebel was of such character as to endanger public health, they had the right under the police power of the city to prevent the sale. While technically the letter of the restraining order may have been violated, this court is not so sensitive of its power as to stand in the way of officers in protection of the public health.'

"Judge Coon is to be congratulated upon his decision not to permit the technicalities of the law to interfere with the duties of health officers in protecting the public health."

# FOR ALCOHOL AND DRUG ADDICTS

Provides a definite eliminative treatment which obliterates craving for alcohol and drugs, including the various groups of hypnotics and sedatives.

Physicians are invited to be in attendance on their patients. Complete bedside histories are kept.

Department of physical therapy and well equipped gymnasium. Located directly across from Central Park in one of New York's best residential sections

## An Invitation to Physicians

Physicians in good standing are cordially invited to visit the Battle Creek Sanitarium and Hospital at any time for observation and study, or for rest and treatment. Special clinics for visiting physicians are conducted in connection with the Hospital, Dispensary and various laboratories.

Physicians in good standing are always welcome as guests, and accommodations for those who desire to make a prolonged stay are furnished at a moderate rate. No charge is made to physicians for regular medical examination or treatment. Special rates for treatment and medical attention are also granted dependent members of the physician's family.

An illustrated booklet telling of the Origin, Purposes and Methods of the institution, a copy of the current "MEDICAL BULLETIN," and announcements of clinics, will be sent free upon request.

## THE NEW YORK STATE PROGRAM IN VENEREAL DISEASE CONTROL\*

By ALBERT PFEIFER, M D, ALBANY, N Y

**T**HE trend of state activities in venereal disease control during the last few years has somewhat resembled a weathervane with its frequent changes. The main cause has obviously been economic, state governments not appropriating sufficient funds to take the place of the discontinued federal allotments rather than for any real difference in opinion as to the effectiveness of the measures used initially, which had the endorsement of the United States Public Health Service. These measures naturally fall under the following headings (1) medical, (2) educational, (3) legal, (4) recreational and protective.

The State of New York early recognized the gravity of the venereal disease menace and made appropriations sufficient to carry out a sane, well-balanced program adaptable for a peace-time campaign. In 1918, the state legislature passed the following statute, Chapter 342, Laws of 1918.

Section 1 "There is hereby established in the state department of health a bureau of venereal diseases

Section 2 "Said bureau shall be under the direction of the state commissioner of health who shall appoint all necessary employees thereof and fix their salaries. Said bureau shall be authorized to buy, manufacture and dispense under such conditions as may be prescribed by the state commissioner of health remedies for the treatment of venereal diseases, to examine specimens submitted to it, to make all necessary tests, provide and distribute literature and to use such other means as seem desirable for the instruction of the public and the suppression and cure of venereal diseases, and to take such further action as seems necessary to secure this end."

*Title of Division Changed*—An outline will be given of the work as conducted by the Division of Social Hygiene, formerly known as the Division of Venereal Diseases. The term "social hygiene" more accurately denotes the activities and is more harmoniously received by the general public than the former name "venereal diseases." The original grouping of gonorrhea, syphilis and

chancroid together under the term "venereal diseases" rested upon the fallacy which regarded these diseases as etiologically similar, an error our modern knowledge has rectified. During the course of the last year a marked change in public opinion toward this subject has been noted. It now appears to be a much sought-after and popular subject. The explanation for this is probably the dignified and conservative manner in which it has been presented by the staff of this Division. Official health authorities and the general public now see gonorrhea and syphilis as a public health problem aside from a question of morality, which makes it amenable to an open attack with a good chance for the success of our efforts. The tremendous task and responsibility involved in the attempt to control and ultimately eradicate these diseases has been appreciated fully from the first. The various factors and insidious ramifications of influences which directly or indirectly tend to spread these diseases make their control extremely difficult. There must be a varied constructive program to combat the many forces which are keeping up the high incidence that we still have today. Such an extensive program requires the active participation and cooperation of all official and volunteer agencies interested in improving social health conditions.

*Personnel*—The staff of the Division of Social Hygiene consists of a director (a physician), an assistant director (college graduate), three lecturers (physicians, two men and one woman), two graduate nurses, one supervising, social service activities and lecturing to special groups such as undergraduate and graduate nurses and the other conducting special social service demonstrations, and office force consisting of secretary (college graduate), one statistical clerk, three stenographers, three typists and three clerks.

*Statistical Deductions*—While none of our available statistics present a true picture of the incidence of gonorrhea and syphilis, yet they do show that

1 These diseases are more prevalent than any other communicable disease (Chart No I—Leading Communicable Diseases)

\* Read at New England Health Institute, October 1, 1926, Concord New Hampshire.

- 2 There is no marked decrease in new infections (Chart II)
- 3 They are diseases of youth
- 4 There is an increase in the number of physicians prepared to diagnose and treat these diseases

CHART I Leading Communicable Diseases

- 5 The public is beginning to appreciate that the control of these diseases is an urgent public health problem

*A Remedial and Constructive Program*—Naturally a program for the control of syphilis and gonorrhea must provide measures for

- 1 The actual infected cases
- 2 The potential cases

The first group, the actually infected, must be first considered, for primarily the control of syphilis and gonorrhea is a medical problem and facilities must be provided to encourage all cases to seek early diagnosis and treatment. It is fundamentally important that acute cases should be brought under treatment early that they may not be a menace to the community and that the chances of ultimate cure may be increased. With these diseases every endeavor should be made to carry on the treatment, particularly in the case of syphilis, until a cure is established or the condition arrested and not to be satisfied that actual infectiousness is not apparent, because we now realize that large numbers relapse when anything less than thorough and complete treatment is administered. Fifty-three clinics have been established in strategic positions and more are contemplated throughout the State to take care of indigent cases. We have provided in most instances the equipment in these clinics and supply the arsphenamines. The local health departments carry the general running expenses (Chart III—Map Showing Clinics and Laboratory Facilities). Monthly reports are made by the clinics to the Department, copies of which are in turn forwarded to Washington (Chart No IV—

Clinic Activities Shown) Visits are made by the Director and also by the social worker from the Department to discuss diagnosis, treatment, follow-up work, record keeping and general clinic management. The number of treatments at the clinics have averaged in the case of syphilis 9.9 per patient, of which 4.3 were one of the arsenicals, 5.6 mercury or bismuth. In the case of gonorrhea the patients averaged 11.3 treatments each. With improved social service this number will undoubtedly be increased (Chart No V—Clinic Treatments). Special efforts have been made to have cases of congenital syphilis treated. In many cases special hours or days are set aside for these cases. The number under treatment has increased from 240 in 1923 to 251 in 1924 and 338 in 1925. Routine blood examinations are recommended in all cases of pregnancy. Particular emphasis is laid upon the value of social service in clinics, which is usually conducted by a nurse. The sources of infection are ascertained whenever possible. In the counties of Cattaraugus, Allegany and Clinton, the clinics are on a county basis, that is to say, supported and conducted by the county. This is an ideal arrangement as facilities are thus provided to reach patients covering a wide area and by county nursing service a more effective check-up can be made on the attendance of patients. The idea of a county as a general health unit is encouraged and undoubtedly in time will extend to all counties. Local boards of health

## NEW CASES OF SYPHILIS AND GONORRHEA UPSTATE BY YEARS

CHART II New Cases Upstate by Years

CHART III. Map Showing Clinics and Laboratory Facilities

by statute must provide treatment for indigents with gonorrhea or syphilis in an infectious state. This is mostly applicable in the large rural areas which are more or less inaccessible to treatment centers. The Department provides the arsenicals required for the treatment of syphilis. Sulpharsphenamine is usually supplied in these cases as it requires no elaborate apparatus for its technique and administration.

*Cooperation of Physicians*—Every effort is made to aid the general practitioner in his diagnosis and treatment. Information regarding new diagnostic procedure, the latest pharmacological preparations and unusual methods of treatment is disseminated through lectures, letters, reprints and in timely articles in the Department's weekly publication "Health News" and in the State Medical Journal. The addresses at medical meetings are illustrated by slides, technical films, moulages or by actual cases. The circular letters emphasize salient points frequently overlooked and invite attention to worth-while current articles.

The outstanding feature last year was par-

ticipating with the State Medical Society at its annual meeting, the entire last day of which was devoted to the consideration of syphilis from every angle in all its forms and manifestations. The unusual interest was manifested by the large attendance, more than 500, over 100 of these registering on this, the last day of the meeting. The Director assisted in preparing a booklet entitled "Fundamentals of Syphilis." About 20,000 copies were sent under the frank to doctors in the State and in adjacent territory.

*Method of Reporting*—The reporting of cases is by the indirect method. The Sanitary Code provides that "every physician shall submit promptly to the laboratory of the State Department of Health or to a laboratory approved by the State Commissioner of Health for this purpose such specimens for laboratory examination and such data relating thereto, as may be prescribed in the special rules and regulations issued by the State Commissioner of Health from every person affected with or suspected of being affected with syphilis, gonorrhea or chancroid." The number of physicians who are known to be

submitting blood specimens or smears to approved laboratories is about 40 per cent of the total number registered. There can be no doubt as to the increasing attention that is being given to the diagnosis of these diseases. During 1925 the late cases of syphilis reported exceeded those of the previous year by 500. In one city every physician was known to have submitted specimens (Chart No VI—Examinations in Laboratories).

*Clinics as Teaching Centers*—The use of clinics as teaching centers for physicians and for the patients is advocated. Physicians are encouraged to attend for instruction and to send to the clinic patients that are unable to pay for all the treatment that may be necessary. A social service that finds patients who can pay a fee and sends them to physicians helps greatly to obtain the necessary cooperation of practitioners. Social hygiene literature can be disseminated through the venereal disease clinics.

*Druggists Discontinue Sale of Nostrums*—To further insure none but scientific treatment for patients, the handling of nostrums and proprietary quack preparations by druggists has been strongly disapproved. The entire state has as yet not been covered, but the Department's representative working in conjunction with the Milbank demonstrations in the city of Syracuse and in the county of Cattaraugus has been highly successful. In Syracuse the majority of the druggists immediately discontinued stocking

CHART V Clinic Treatments

these preparations while the local pharmaceutical society promised complete success by the end of the year. In Cattaraugus County every druggist was willing to cooperate, and stock valued at over a thousand dollars was destroyed or sent back to the wholesalers or manufacturers.

(Chart No VII—Diseases of Youth)

In examination of the gonorrhea cases for males according to age it is noted that there are few cases in any one year until the 14th and 15th years, and after that the number rises rapidly until the 22nd year, when it reaches its maximum. In the case of females the cases are much higher from 1 to 10 years than from 10 to 15. In the 15th year there is again a marked increase when the number of gonorrhea cases is three times the number in the 14th year and continues to rise until the 22nd year with the exception of the 21st year when the number is one less than for the 20th year, which is of no statistical significance. The fact that the cases have increased so materially in the 14th year for boys and in the 15th year for girls indicates that at these ages there is some new factor operating in spreading these contagious diseases. Probably this new factor is due to sex promiscuity among adolescent youths. If the marked increase in the incidence of syphilis and gonorrhea at the beginning of puberty is due to sex promiscuity, then constructive measures for preventing the spread of these diseases, such as character building and training in sex hygiene must be given to the youths before they reach the age of 14. (Chart No VIII—Sex Delinquency). Sex education is for the protection of boys and girls and should be given before they are exposed to temptations. Failure in giving such instruction and developing the sense of social responsibility in adolescent youths places the responsibility for these infections upon parents, educators and society in general.

## CLINIC ACTIVITIES

### NEW CASES

CHART IV Clinic Activities Shown.

CHART VI. Examinations in Laboratories

*The young people who have not had sex information imparted to them and have not had positive, dynamic and impelling reasons given for living in a way that will meet their approval years later are not immoral, if they have loose sex relationships, but rather immoral*

**Educational Measures**—An effective public health program must include educational measures. In the case of social hygiene this must of necessity be a many sided and difficult task. It includes <sup>1</sup>

<sup>1</sup>Vide, 1925 Annual Report, Division of Social Hygiene, N. Y. State Department of Health.

CHART VII Diseases of Youth.

1 The convincing of local health officers that the control of syphilis and gonorrhea is a local problem for which they are responsible and at the same time giving them an effective and yet practical and workable community program

2 The supplying of physicians with the latest information regarding diagnosis, prognosis and treatment, and emphasizing persistently the public health aspect of control measures to the medical profession

3 The disseminating of extensive propaganda among the lay people so that they will recognize the control of syphilis and gonorrhea as an urgent public health problem and will be willing to support official and volunteer agencies in their activities and initiate and participate actively in such phases of the work as may be necessary in order to protect the public and prevent new infections

CHART VIII Sex Delinquency

These various ends are accomplished chiefly through interviews, lectures and publicity

Through interviews, officials and influential persons are made to see that they are responsible for the control of these diseases in their community. The incidence of syphilis and gonorrhea can be reduced materially only when each community recognizes it as a local problem

**Lectures**—The giving of lectures has in general three aims

1 In communities not interested in social hygiene, talks are given to impress the public with the menace of syphilis and gonorrhea and the need for their control. This was the most important phase of educational work when the Division was organized but since this phase of public health is now recognized by all progressive communities, this type of lecture has been superseded in general by those of a more specific character

2 In communities already interested in social hygiene where there is a group of influential men

and women prepared to initiate and carry out on a permanent basis a practical social hygiene program, lectures are given in order to develop a public opinion for the support of these leaders in their various activities

3 Lectures are given to demonstrate how educational work can be initiated, developed and carried out successfully. Examples of such types of lectures are those given in colleges, normal schools and high schools. The purpose here is not primarily to impart information or to develop character in the individuals but rather to give a concrete example to the faculty, of the subject matter and method of presentation with the idea that the work will be carried out afterwards by the professors or teachers of the institutions. Sometimes it is necessary or desirable to give such a demonstration in the same institution for two or even three years, but if the work is successful, it should become within that period an integral part of the curriculum under the direct supervision of a resident member of the faculty. The state lecturers released from this group seek to interest other educational groups. This is a somewhat slow but effective way of getting this phase of personal hygiene incorporated permanently in the school and college courses of instruction.

The most notable achievement in the lecture field during the year was having the State Parent-Teacher Association feature social hygiene in their local clubs. It is evident that the officers responsible for making this cooperative arrangement between the State Parent-Teacher Association and this Division did not misjudge the desire of their membership on this question, since the educator assigned to this work for a period of three months was literally flooded with requests. Definite bookings were made for a year ahead and the requests continued to come. The rapid growth in the demand for lectures by the Parent-Teacher Association is shown by the fact that in 1923, five lectures were given, in 1924, 22 lectures, and in 1925, 72. The speaker detailed to meet these groups has been unusually successful. Approximately one-eighth of all the women attending these meetings have taken the trouble to write for literature covering the various phases of the subject and many of the groups have arranged for the speaker to address high school girls. The Parent-Teacher Association has 577 local clubs with an aggregate membership of 33,758. It is obvious that this is one of the most important groups to reach in a social hygiene educational program.

1 Because it is the privilege and responsibility of the parents to impart sex information and develop the character of their children,

2 Because the teachers should recognize sex problems as such and know how to meet them successfully

3 Because parents and teachers will perceive that all children will not get proper instruction at home. Hence the parents will request necessary school instruction in social hygiene and teachers should be willing and able to accept this responsibility,

4 A study of the social hygiene measures necessary to make education an effective prophylaxis will convince these groups that few parents are both able and willing to inform and guide their children satisfactorily. Most parents are either unwilling, although able, or else unprepared for this training of adolescents. For these reasons it is apparent that it will be a long time before the majority of children receive sex instruction in the home, although this would be the ideal place. The effectiveness of universal home instruction cannot be estimated, for even those receiving excellent home training have the destructive influences of their playmates to combat. For the sex attitude of youths trained properly in sex matters will not be respected or understood by their untutored comrades, and they will be subjected to the ridicule and vulgar sex discussions of their associates whose sex training has been lacking in truth, purity and idealism. If the youths as a group are to be protected from syphilis and gonorrhea through education and character building, all youths must share in this training. Thus it will be seen that when the Parent-Teacher Associations appreciate the importance of this work, they will desire to have a sound practical method of sex instruction in the schools, the teachers will be familiar with the reasons for sex instruction and the school authorities will realize that in incorporating such courses in the curriculum, they have the whole-hearted endorsement of the parents. Simultaneously with the creating of a demand for school instruction in social hygiene there should be carried on a program for the training of teachers. The Division is cooperating with normal schools in the training and developing of teachers for this fundamental and essential instruction.

*Publicity*—Although interviews and lectures are the best and most efficacious ways of disseminating information, these methods have decided limitations.

For example, the personnel of the Division's staff of educators is insufficient to reach more than a small proportion of the people. In the last seven years only one-tenth of the number of people upstate have been reached by lecturers. Obviously, it is impracticable to depend solely upon a means of public education which would require seventy years to reach the entire population once.

Since the educators can reach at best only a small percentage of the people, it is desirable for them to work in the larger communities

where the attendance at the lectures will be reasonably large in order that they may reach the greatest number in the least possible time. This means that rural communities must be neglected largely. To illustrate, during the past seven years lectures have been given in only 576 communities although there are approximately 2,500 post offices upstate.

In the endeavor to reach so far as possible adolescent youths and those directly responsible for the guidance of these young people, it usually results in having an opportunity to address a particular group but once. The formation of character, the creating of good habits or the abolishing of bad habits is a tremendous task and little permanent good along these fundamental lines can be accomplished in a single lecture.

In presenting this intricate subject in a formal address, there is a tendency for the speaker to err in one or two ways. The talk is either centered around a few essential facts and the entire problem seems simple or else the many phases of the subject are touched upon, revealing the complexity of the problem and overwhelming the individual who feels that the control of these diseases is practically hopeless and that the little a single individual can do is hardly worth while. These hazards are being avoided by employing experienced and qualified lecturers.

The cost per person reached by educators through interviews and lectures is so high that there is little possibility of increasing this service. Therefore the present aim is to concentrate on developing leaders rather than reaching large general groups.

These are some of the outstanding reasons which make it necessary to supplement this educational work by other means if there is to be any hope of reaching the public in general. Some activities which have been tried and found to complement the work of the educators to some degree are circular letters, radio talks, informational pamphlets and newspaper publicity.

*Circular Letters*—A year ago the possibility of supplementing the activities of the educators by means of circular letters to the lay people was considered favorably and initiated. A modest mailing list of approximately 5,000 names was gotten together and four or five letters sent. From the very start there was an unexpectedly large response to these circular letters, which were most favorably received and the aims of the Division were highly commended. The unexpectedly liberal response to these letters was convincing evidence that they filled a real need and encouraged the Division to continue and enlarge this feature. A more comprehensive mailing list of approximately ten thousand names was developed. The list was made up of about an equal number of men and women residing in more than nine hundred communities. Great care was exer-

cised in selecting the names and each was keyed for checking purposes. In general the list was made up of officials of health organizations, judges, librarians, superintendents of schools, principals of high schools, public health nurses, officers of volunteer welfare associations, men and women responsible for guiding adolescent youths, presidents of associations such as the Parent-Teacher Associations, women's clubs, luncheon groups, etc.

There are many advantages in having a mailing list known to be composed of intelligent broad-minded people, interested in civic improvement. The letters can be frank and direct, giving a definite and scientific statement of the problems with suggestions as to how these have been met successfully in certain communities. A single point can be stressed in each letter. The letters may be made progressive. All of the people addressed are interested in social betterment and can reasonably be expected to be willing cooperators in the control of syphilis and gonorrhea and especially in their prevention when they understand the urgency of the problem. Although the success of the circular letters the previous year had given an assurance of the desirability of this feature, it had not prepared the Division for the tremendous response it was to receive from this new series of letters. Some of the tangible results from this rather brief and limited campaign of publicity will give an idea of the response of the public to this feature.

Although no attempt was made to have the letters appear other than form letters, each one brought many replies, invariably commending the activities of the Division and expressing satisfaction at having the information sent in that particular letter. For example, one of the letters brought a request for literature and information from a person in charge of selecting the reading material for a group of fifty thousand men.

This particular letter brought requests for either pamphlets or further information from over twelve hundred other people residing in more than four hundred different communities.

Another letter created considerable interest in the lecture activities of the Division and brought definite requests for lectures to groups augmenting more than twelve thousand. These were all organizations not previously reached.

The recipients, from time to time during the year have sent in more than one thousand names of friends to be added to the mailing list. In this manner the Division has been put in touch with some very influential people who are directing health and welfare activities in their respective communities. The physical director of the public schools in one large city requested that the seventy-eight instructors under his supervision be sent a copy of a particular letter. Nu-

merous superintendents of schools have sent, unsolicited, the names of all teachers under their jurisdiction to be added to the mailing list. A number of people who have moved out of the State have written expressing a desire to have their names continued on the list. Others from outside the State who have found out in some way about this educational service have asked to receive the letters, justifying their requests by their official positions and ability to make the information available to numerous others within their respective communities.

This form of publicity certainly has some definite advantages over any other educational work. It is possible to reach the people responsible for the health conditions of their communities. Those influential people who ultimately determine the social conditions in their towns can be informed regarding the menace of syphilis and gonorrhea. Each person can be reached four to six times during the year and not have to depend upon one contact. Repetition has a definite cumulative effect. The communications may be written to meet definite emergencies and the interests of people in every part of the State may be secured simultaneously. The known leaders of hundreds of communities are addressed, multiplying the effectiveness of the work many fold. The majority of the persons reached would probably not come in contact with this work in any other way. The rural communities can be definitely served. The cost per letter or even for the series of letters is only a small fraction per capita of what it would be for a lecture.

*Radio Talks*—The potential possibility of the radio for reaching people in the remotest parts of the State and those who probably would not be in contact with the activities of the outside world to any great extent, arouse many fascinating speculations in the mind of a publicity man. However great the possibility may be in such publicity, some persons felt that it would be impossible to give a social hygiene talk which would be both acceptable and of real value. That the subject of social hygiene has no inherent obstacle which cannot be overcome in preparing a radio talk has been shown definitely. Two such radio talks were given last year, each pointing out in a very definite and unmistakable manner certain social hygiene problems and suggesting ways for meeting these conditions. An unusually large number of local newspapers throughout the State mentioned these talks. Many requests for literature resulted directly from the talks and indirectly from the newspaper reports. One statewide organization in the Middle West determined to feature social hygiene in its educational program during the coming year, after reading the report of the talk, and wrote to the Division for specific information. Unquestionably this is a field which can be developed and

utilized more extensively. A series of social hygiene talks have been approved and will be given from WGY during the coming year.

*Pamphlets*—An attempt during the past two years has been made to work out a practical plan for the profitable distribution of pamphlets. Although the plan is yet in the formative stage, the marked success with which it has met warrants an outline of the procedure. There was a constant decrease in the number of pamphlets distributed from 1919 to 1924 inclusive. During 1925 there was a marked increase, about one-third more pamphlets were distributed than during the preceding year. When the Division was first established, pamphlets were distributed rather generally on the theory that a certain per cent of them would be read and therefore the larger the distribution, the larger the number of copies read and the greater the dissemination of the information. Undoubtedly this was true to a great extent. However, it was a rather expensive manner of reaching the masses of people.

Last year, there was no general distribution of pamphlets, but instead certain selected mailing lists were circularized and a definite effort was made to let the public know what pamphlets were available, through the distribution of postcards for requesting the literature. It was through the postcards that the increase in pamphlets distributed can be most largely attributed. Another factor was the issuing during the year of several new pamphlets.

The number of requests for literature by years shows a rather definite progressive decrease year by year from 1919 until 1924. In 1924 the number of requests would have been even less if the efforts for stimulating this phase of the work had not been inaugurated. About 600 of the requests for 1924 could be traced to a definite publicity campaign. For the year 1925, the number of spontaneous requests received in Washington and in Albany were about the same as for the preceding year, namely about 2,000. The other 5,200 requests are known to have resulted from certain definite efforts of the Division, namely, 841 requests were the result of lectures and the remaining, approximately 4,400, were due to the publicity campaign carried on by the Division. Although the program for publicity and distribution of literature is not perfected, the results for the past two years are sufficient to warrant the following conclusions: (1) that the public is eager for information and will take the trouble to write for literature if they know where to write and what is available, (2) that a publicity campaign along constructive lines will meet with more than fair success—out of 10,000 people circularized several times, more than 4,000 took the trouble to write in, commending the work or requesting literature, (3) that the distribution of literature in response to spe-

cific requests is not only more economical but also more effective

*Use of the Daily Press* — Effective advance copy relating to the speakers and subject matter augments materially the attendance at the lectures and a report of the principal points emphasized in the address is always welcomed by progressive newspapers. Thus, it is possible to have at least two news items for each lecture. Frequently the attendance at a lecture will not exceed fifty persons but the newspapers in the same community may be read by several thousands and if the lecture is reasonably well reported, and it will be if the lecturer provides the papers with acceptable copy, at least a few cardinal points will be gotten across to the much larger reading public. By incorporating into the news items a statement regarding the available pamphlets a proportion of the readers will request literature. There is no phase of the general education more important than getting the newspapers to announce and to report lectures. In this manner the masses are reached directly through a medium acceptable to them.

During the past year one hundred and twenty-nine articles were carried by various newspapers

which have endorsed, supported and advanced the Division's constructive program

*Legal Measures* — While the general effectiveness of public health activities depends mainly upon an enlightened public opinion, a certain amount of legislation is necessary. There is always a small percentage of more or less recalcitrant individuals, to control whom special legislation seems required. The present laws and regulations governing gonorrhea, syphilis and chancroid are deemed adequate and have been compiled and printed in pamphlet form for distribution to all interested. In many instances the enactment of statutes has an educational value. An example of this is the Domestic Relations Law which requires city and town clerks to obtain from each of the contracting parties applying for a marriage license, a signed statement that they have not been infected with a venereal disease, or if infected within five years, that the laboratory tests are now negative. Prostitution is not legally sanctioned and there are no authorized red light districts. The Division keeps in close touch with probation officers and judges in a consulting capacity regarding policy and enforcement of legislation.

## THE ROLE OF CARBOHYDRATES IN INFANT FEEDING\*

By LINNAEUS EDFORD LA FETRA, M.D., NEW YORK, N. Y.

**C**ERTAIN facts about the carbohydrates are so well established and so well known as not to need discussion, viz

1 That the sugars, dextrans and starches are the most economical source of energy, some being absorbed as ingested, and others requiring but little digestive effort.

2 They furnish energy chiefly for heat maintenance and muscular activity, they build up the glycogen reserve and may be converted into stores of fat.

3 They spare proteins, thereby lessening the amount of nitrogen excretion otherwise necessary, moreover they may, to a certain extent, be utilized to build up certain useful amino-acids.

4 They can replace the fats to a very large extent—up to the point of not causing deficiency in the fat-soluble A and the antirachitic vitamins.

5 They serve, when properly utilized, to prevent acidosis.

Certain other facts about the carbohydrates are not so well recognized, and it is to these that I wish to call attention, viz

1 The various carbohydrates have different

rates of absorption in the digestive tract, the simpler monosaccharids being absorbed more quickly than the complex sugars, dextrans and starches.

Flood† has shown that, of the monosaccharids, dextrose is most rapidly absorbed, then galactose, and finally levulose, and that the disaccharids maltose, lactose and sucrose, show some of the characteristics of their component monosaccharids. He states further that the absorption of any polysaccharid depends first on the speed and ease with which it is hydrolysed into its component monosaccharids, and secondly, on the specific absorption rate of these monosaccharids. For convenience he classifies the sugars into I those which give only dextrose on complete hydrolysis, and II those which do not. Dextrose does not have to be changed to be absorbed, whereas galactose and levulose must probably be converted into dextrose before being absorbed. This conversion takes time and energy not needed by the dextrose, and meanwhile the galactose and levulose are passing further down the intestinal tract. In the dextrose group are, besides dextrose, maltose, Karo syrup, and dextrimaltose. The maltose consists of 2 molecules

\* Read at the Annual Meeting of the Medical Society of the State of New York, at New York, March 31, 1926

† *Jour. Amer. Med. Assoc.*, May 17, 1924, page 1595, and *Archiv. of Pediatrics*, January, 1925, page 50

of dextrose, the Karo syrup consists of 34 to 36.5 per cent dextrose, 4 to 19 per cent maltose, and 29 to 45 per cent Dextrin. Dextrin-maltose contains about equal parts of dextrans and maltose, but has no immediately available dextrose. All the members of this group have a comparatively rapid absorption time, and therefore are less apt to reach the lower bowel where fermentation takes place. They are useful, especially dextrose, in fermentative diarrheas, particularly those accompanied by acidosis.

In Group II, lactose and sucrose are broken up into galactose and dextrose and into levulose and dextrose respectively. Their laxative action can be explained partly by the slower rate of absorption of their component galactose and levulose, and partly by the deficiency of the respective hydrolytic enzymes during the early months of life.

Honey is a mixture of dextrose and levulose with the levulose predominating. The dextrose is quickly utilized, but the levulose being more slowly absorbed passes further down the intestine and may reach the colon, where its fermentation produces a laxative effect. It is seen then that the dextrose group is readily absorbed and has little laxative effect, the lactose-sucrose group is poorly absorbed and has a marked laxative effect, while honey occupies a middle position, part being readily absorbed, while another part is poorly absorbed and has a laxative action.

The dextrans and starches must undergo further changes to be converted into maltose and finally dextrose, hence they pass further down the intestine before being absorbed, if in excess, the starch, the dextrin and even the maltose or dextrose may reach the colon.

2 The different sugars, until absorbed from the intestinal tract, have special tendencies to different types of fermentation.

Many years ago Rotch called attention to investigations by W. G. Aitchison Robertson\* on the main types of fermentation the various sugars are prone to undergo. They can be arranged in accordance with the rapidity and ease with which they become converted into lactic acid, butyric acid, and alcohol or acetic acid as follows:

<i>Lactic Acid</i>	<i>Butyric Acid</i>	<i>Alcohol and Acetic Acid</i>
Levulose	Levulose	Maltose
Lactose	Maltose	Sucrose
Dextrose	Dextrose	Dextrose
Sucrose	Sucrose	Levulose
Maltose	Lactose	Lactose

It is seen that levulose and lactose are most prone to lactic acid fermentation, maltose least so, levulose also most readily undergoes butyric acid fermentation, lactose least, while maltose is most prone to alcoholic and acetic fermentation, lactose least so. Dextrose occupies a

middle position throughout. These observations would suggest the advantage of substituting maltose for lactose in cases of lactic acid fermentation and of using lactose instead of maltose in both butyric and acetic fermentations.

A consideration of these tendencies to fermentation is of interest when taken in connection with the rate of absorption of the various sugars. Dextrose is most readily absorbed but has but slight tendency to fermentation, it is therefore the sugar of choice when one wishes rapid absorption and desires to avoid fermentations. Mixtures of the various sugars and other carbohydrates tend to prevent any single type of fermentation, being gradually hydrolysed they are absorbed at different levels down to intestinal tract. In cases of putrefactive disturbance, moreover, the sugars encourage the growth of antagonistic fermentative bacteria, especially those forming lactic acid. This is of advantage not only in putrefactive conditions, but also as Torrey has shown in cases of typhoid fever, the lactic acid bacteria being antagonistic to the typhoid bacilli.

As regards dextrose now available at a cost of about 50 cents per pound, I have used it with great satisfaction in many cases of diarrhea and mal-nutrition, substituting dextrose for the other sugars added to the milk. I need only allude to the successful employment of dextrose parenterally, either by the intravenous or intraperitoneal route in severe cases of dehydration, of cyclic vomiting and of acidosis, either without or with the administration of insulin. The use of Karo syrup, especially in lactic acid milk, has been popularized by Marriott.

Thick cereal feedings have been used with remarkable success in cases of rumination and of pylorospasm, they owe their success probably not only to their thickness and bulk but also to the mixture of various carbohydrates they contain. The banana has been used for years for infant feeding by people of the tropics, and the Cubans have also a banana flour which is very popular. Pease† in 1917 called attention to the value of fully ripe or baked banana as a carbohydrate for young children, and since that time it has been more widely used. Haas has emphasized its value in the malnutrition of coeliac disease. Ripe banana contains 22 per cent of carbohydrate largely sucrose, with a caloric value of 447 per pound—somewhat more than white potato which has a value of 378 calories per pound, and less than sweet potato with 558 calories per pound. The absorption in Pease's cases was almost complete—98 per cent.

Mixed sugars including honey are especially valuable in older infants that have constipation.

\* *Edinburgh Medical Journal* March, 1894 page 803

† *Am. J. Diseases of Children* November 1917 page 379

with gaseous distension of the abdomen from eating too much bread and potato

In fevers where there is always a tendency to depletion of the glycogen reserves and hence to acidosis, dextrose and the other readily absorbed carbohydrates have an important function. In typhoid fever, where a high calory diet is advisable, they are especially valuable.

The acidosis occurring after operations, whether due to vomiting or to interference with liver function, is fortunately less frequently seen, since the practice of pre-operative starvation has been abandoned. In children, however, who are so susceptible to acidosis, not only should there be no starvation period, but special effort should be made to increase the carbohydrate in the body. Operations on children should, if possible, be done in the early morning. Supper on the preceding night should contain a large quantity of carbohydrate—mixed sugars and starches, during the night or very early in the morning the child should have several ounces of orangeade or lemonade, sweetened with dextrose. This will not only build up the carbohydrate reserve, but will add water and alkali—all very important in preventing acidosis or the excessive vomiting which may result in acidosis.

3 Carbohydrates should be furnished in the diet of infants and children to the amount of about 50 per cent of the total calories.

Powers,\* in an analysis of the various milk mixtures used for infants, found that the combinations most successful do not resemble breast milk, but rather dilutions of condensed milk or Pirquet's "dubo" mixture, in which to whole milk 17 per cent of sugar is added. In this majority group, instead of 50 per cent added sugar, as in "dubo," 40 per cent of the calories are added carbohydrates, 60 per cent being furnished by whole milk. The distribution of the calories showed protein about 13 per cent, fat 30 per cent and carbohydrate 57 per cent. In some cases the carbohydrate was as high as 75 per cent, 15 per cent being fat and 10 per cent protein. Malt soup mixture No 1 contains 14 per cent protein, 14 per cent fat and 73 per cent carbohydrate. Higher protein and fat with less carbohydrate would seem desirable as a rule, especially with young infants.

Holt\* investigated healthy children from 1 to 18 years of age and found the distribution of the calories was on the average protein 15 per cent, fat 30 per cent, carbohydrate 51 per cent of which carbohydrate a little over one-half was given as sugar. Gebhart found that the healthy active boys of St Paul's School consumed 600 grams of carbohydrate daily, or nearly 2,500 calories per day, much of this being in the form of sweets bought at the tuck shop. The craving for sugar on their cereals, for sweet foods and for candy is physiological, but sugars should not be permitted in the diet in such quantity as to diminish the needed proportion of protein and fats, nor so as to disturb the appetite or digestion. In this connection it may be noted that Mahler has shown that while galactose, dextrose and maltose are fairly strong stimulants to gastric hydrochloric acid secretion, and 5 per cent sucrose also is a good stimulant, a 20 per cent solution of sucrose uniformly lowered the HCl output. Excess of sugars lessens the appetite and may result in vomiting or diarrhea, excess of starches is apt to result in gaseous abdominal distension and constipation. Moreover, as Holt has pointed out, dental caries may be one result of excessive sugars in the diet, since Arctic peoples who subsist largely on proteins and fats seldom suffer from defective teeth.

Finkelstein† has emphasized that though carbohydrate does not itself enter into the composition of cell protoplasm it induces retention of protein salts and water, being the chief influence by which water and water-containing constituents are stored in the tissues. In infants of the hydrolabile type, therefore, the carbohydrate should be reduced, the fats increased and the proteids kept at a moderate amount. In such infants the weight curve should be kept rising at only a slow rate. In cases of the exudative diathesis, also, the carbohydrates should be kept low.

Knowledge of the foregoing facts should be useful in correcting many digestive disturbances, in securing gains in weight, and in preventing or overcoming acidosis.

# THE VITAMIN VALUE OF SOME COMMON FOOD STUFFS\*

By WALTER H EDDY, Ph D, NEW YORK, N Y

Professor Physiological Chemistry, Teachers College, Columbia University

AS the Science of Nutrition advances and as popular knowledge of its laws increases this progress is reflected in the advertising of the food manufacturer. What was for a time pure psychology is becoming, at least in part, physiology. I mean by this that instead of basing his appeal solely on form and the laws of mental appeal, he is rapidly coming to include a more careful statement of the values of his product. He is quick to realize that the public with its new knowledge isn't going to believe claims that are too sweeping and that they wish to know just what his product contributes to the diet. Such data is impossible either in text or advertisement without quantitative assay of food values.

In the case of calorie values, nutrient content, and the like, such values have been available for some time. The advent of the vitamins, their kind and effects is, however, recent science. The development of adequate assay methods is still in process of evolution. On that account it has seemed worth while to review today some of the recent findings in this field of assay and some of the difficulties that we are meeting in developing the type of analysis desirable.

I will take my first example from some experimentation just completed in my laboratory on the antiscorbutic value of ripe bananas. Before this work was begun there had been so far as I can learn only two such studies and both of these with basal diets since shown to be lacking in other factors than vitamin C. Also in both these studies the conclusions stated amounts that would protect experimental animals (10-15 grms) but not the minimum protective doses. Lack of this latter data made impossible quantitative comparisons with other sources of the vitamin.

Much of the methodology that is advancing the accuracy of vitamin analysis is the product of the laboratory and students of Professor Henry C Sherman of Columbia University. To Sherman and LaMer we now owe a basal diet which contains all known factors necessary to the life of the guinea pig except vitamin C. This diet consists of the following ingredients:

Ground whole oats	59 parts
Vitamin C—free skim milk powder	30 parts
Butter fat . . .	10 parts
NaCl	1 part

It is with the aid of this diet that we have

within the past three years studied the antiscorbutic value of many foodstuffs. Table I gives some of the results to date.

TABLE I  
SOME VITAMIN C VALUES RECENTLY DETERMINED<sup>1</sup>

Food Stuff	Min Protective Dose	Comparisons in richness
Standard (Orange Juice)	1.5-3 gms (unit 2 gms)	10
Bananas (raw and ripe)	5 gms.	0.4
Bananas (yellow baked in skins)	less than 6 gms	0.2
Apples, fresh picked	10 gms	0.2
Apples, cold storage	20-40	0.1-0.05
Canned apples	7-40	0.5
Canned apples, brine treated	20	0.7
Cabbage, raw	10 gms	2.0
Cabbage, boiled	20 gms	0.1
Cabbage, canned	4 gms	0.5
Spinach, raw	1/4-1 gm	2.8
Spinach, cooked on stove	10 gms	0.2
Spinach, canned	2-4 gms	1-0.5
Peas, raw	2	1
Peas, stove cooked	5	0.4
Small peas, canned	3	0.66
Large peas, canned	4	0.5
Ave. peas, canned	3	0.66
Ave. peas, canned, reheated for table	3	0.66
String beans	5 gms	0.4
Small string beans, canned	20 gms	0.1
Large string beans, canned	over 30 gms	0.08
Home cooked string beans	20 gms	0.1
Sweet corn, raw	5 gms	0.04
Sweet corn, boiled on cob	10 gms	0.02

Much of interest to assay technique as well as to knowledge of vitamin C has been gained by the studies recorded in the table. To cite a few of them it is of keen interest to learn that a fruit which the researches of Myers and Rose have already shown to be easily digestible if eaten ripe and slowly, even by children of tender age, ranks close to the orange as an antiscorbutic and is the equal in this respect to some of our green vegetables, while it surpasses others.

A fact that was early suggested by Hess, namely that Vitamin C destruction is due largely to oxidation, has been confirmed in many ways by these studies. If for example we bake the banana in its skin it loses much less vitamin C than with the skin removed. Fresh picked apples suffer great loss of this factor in storage for the same cause. Foods sealed in cans before heating may then be heated for long periods at high temperatures with much less destruction to vitamin C than when they are cooked in open kettle, and such foods, due to the low oxygen content, do not

<sup>1</sup> The details of the experiments on which this data is based have been published in part in the Journ Med and Eng Chemistry

\* Read at the Annual Meeting of the Medical Society of the State of New York, at New York, March 31, 1926

suffer the same loss as their fresh oxygen—rich prototypes, even when reheated after removal from the can

Maturity is also seen to be a factor in richness of vitamin C, the younger leaves, seeds and fruits usually proving richer in this factor than the older, more mature forms. One of the most striking of our discoveries in the study of canned products was the efficiency of brine immersion of apples before canning in protecting the vitamins. That this treatment somehow protects against oxidation is indicated, but the methodology is at present a matter of research.

source of B would stimulate greater and lesser growth

In our experiments we have again used a basal diet and a procedure developed in Sherman's laboratory and comparisons based on a gain of 20 grams per period of 56 days per rat. When the richness in B is sufficiently great to permit feeding the source of B separately without reducing the consumption of basal diet to the danger point of inadequacy in other nutrient factors the method works well and permits assay of B value in foods impossible by the normal growth method. Chart I illustrates this method in its working. In the case of the

CHART I The Vitamin A Value of Ripe Banana

The single lines show the individual gains or losses in weight of white rats in a sixty day period using the Sherman-Munsell basal diet and the daily intakes of banana indicated. The heavy lines are averages. Results show that more than 0.4 grams and less than 0.5 grams of banana are necessary to produce a 25 gram weight gain in sixty days when the banana is the sole source of vitamin A and the basal diet complete in all known dietary factors.

But not only in the field of vitamin C assay has progress been made. Practically all the earlier tests used the growth curve of the white rat as an index with a basal diet complete in all known factors except B. In most of these studies however data was expressed in amounts necessary to "normal growth." Now "normal growth" is too great a variable to serve as a satisfactory standard of comparison. Consequently some years ago Drummond of England suggested comparisons at levels of intake which would produce better than maintenance but subnormal growth, definite weight gains for example in a given period of feeding plus evidence that greater or lesser amounts of the

banana it has enabled us to extend the previous work of Sugiura and Benedict who reported the fruit low in this factor, and to demonstrate that while it is relatively low as compared with certain rich sources of B, it is at least half as rich in this factor as good milk, pound for pound, and perhaps richer.

In the study of vitamin A assay also we have had to completely revise our earlier tests because of the discovery that this vitamin is stored in the tissues of the rat and that until freed of this stored vitamin he is almost worthless as a test animal. Our procedure now is to select animals from groups maintained on a uniform diet, to feed them on a basal diet

## THE VITAMIN VALUE OF SOME COMMON FOOD STUFFS\*

By WALTER H EDDY, Ph D, NEW YORK, N Y  
Professor Physiological Chemistry, Teachers College, Columbia University

AS the Science of Nutrition advances and as popular knowledge of its laws increases this progress is reflected in the advertising of the food manufacturer. What was for a time pure psychology is becoming, at least in part, physiology. Also in both these studies the conclusions stated amounts that would protect experimental animals (10-15 grms) but not the minimum protective doses. Lack of this latter data made impossible quantitative comparisons with other sources of the vitamin.

Much of the methodology that is advancing the accuracy of vitamin analysis is the product of the laboratory and students of Professor Henry C Sherman of Columbia University. To Sherman and LaMer we now owe a basal diet which contains all known factors necessary to the life of the guinea pig except vitamin C. This diet consists of the following ingredients:

Ground whole oats . . . . .	59 parts
Vitamin C—free skim milk powder	30 parts
Butter fat . . . . .	10 parts
NaCl . . . . .	1 part

It is with the aid of this diet that we have

within the past three years studied the antiscorbutic value of many foodstuffs. Table I gives some of the results to date.

TABLE I  
SOME VITAMIN C VALUES RECENTLY DETERMINED<sup>1</sup>

Food Stuff	Min. Protective Dose	Comparisons in richness
Standard (Orange Juice)	1.5-3 gms (unit 2 gms)	10
Bananas (raw and ripe)	5 gms.	0.4
Bananas (yellow baked in skins)	less than 6 gms	0.2
Apples, fresh picked	10 gms.	0.2
Apples, cold storage	20-40	0.1-0.05
Canned apples	7-40	0.5
Canned apples, brine treated	20	0.7
Cabbage, raw	10 gms.	2.0
Cabbage, boiled	20 gms	0.1
Cabbage, canned	4 gms	0.5
Spinach, raw	1/4-1 gm.	2-8
Spinach, cooked on stove	10 gms	0.2
Spinach, canned	2-4 gms	1-0.5
Peas, raw	2	1
Peas, stove cooked	5	0.4
Small peas, canned	3	0.66
Large peas, canned	4	0.5
Ave. peas, canned	3	0.66
Ave. peas, canned, reheated for table	3	0.66
String beans	5 gms	0.4
Small string beans, canned	20 gms	0.1
Large string beans, canned	over 30 gms	0.08
Home cooked string beans	20 gms	0.1
Sweet corn, raw	5 gms	0.04
Sweet corn, boiled on cob	10 gms	0.02

Much of interest to assay technique as well as to knowledge of vitamin C has been gained by the studies recorded in the table. To cite a few of them it is of keen interest to learn that a fruit which the researches of Myers and Rose have already shown to be easily digestible if eaten ripe and slowly, even by children of tender age, ranks close to the orange as an antiscorbutic and is the equal in this respect to some of our green vegetables, while it surpasses others.

A fact that was early suggested by Hess, namely that Vitamin C destruction is due largely to oxidation, has been confirmed in many ways by these studies. If for example we bake the banana in its skin it loses much less vitamin C than with the skin removed. Fresh picked apples suffer great loss of this factor in storage for the same cause. Foods sealed in cans before heating may then be heated for long periods at high temperatures with much less destruction to vitamin C than when they are cooked in open kettle, and such foods, due to the low oxygen content, do not

## THE DEBT OF RELIGION TO SCIENCE\*

By HARRY EMERSON FOSDICK, D D

Pastor of the Park Avenue Baptist Church New York

THERE are three great professions, membership in which I envy any man to be a teacher, to be a physician, or to be a minister, because the members of those three professions have the inestimable privilege of serving human life directly, putting themselves into the lives of individuals, and finding their reward in the help which they can bring to and the experience which they can have with individuals.

There are two great philosophies of life it is either a trade or an art. It may be a trade where you see what you get out of it, or it may be an art where you try to do a fine piece of business for the love of high workmanship. And it is the teacher and the preacher and the physician that peculiarly have the opportunity to do that. "You must give yourself to people," said Alice Freeman Palmer, of Wellesley, "and they give themselves to other people and so you go on working forever."

I represent the Church of which Dr. Phillips is a member. As metropolitan parishes go, the number of sheep in that flock is not large, but some of the sheep themselves are notoriously huge and Dr. Phillips is one of them.

How can I speak here, a minister, in the midst of a scientific fraternity of physicians, without thinking of the relationship between science and religion? Only you needn't be nervous. I am not going to talk about it in the ordinary tone of voice, because the ordinary tone of voice seems to be that there is a conflict between science and religion that somehow needs laboriously to be accommodated, whereas my experience is that when I deal with the highest type of scientific man, I find him most reverent, and when I deal with the highest type of religious man, I find him most impatient of credulity, and most desirous for scientific method.

So that tonight I am not going to talk about science and religion as being antithetical, contrary, in discord and disharmony. To be sure, there are certain types of science that have it in for religion.

I suppose that if you do insist on thinking of man as a materialistic mechanism and nothing more, that doesn't leave much place for religion. If we are nothing in the world but just materialistic mechanisms, so that all our thought, all our aspirations, all our ambitions for a better social order, all our science and all our art are as automatic as the sounds that a coo coo clock makes at midnight, it doesn't leave much room for religion.

I am perfectly sure that man is in one sense a mechanism, but it is one thing to be a mechanism like an automobile that you can within limits steer toward directions that you choose, and it is another thing to be a mechanism like a trolley car, that is not only driven from behind, but is set on certain rails that it can never leave. As a whimsical Englishman put it:

"There was a young man who said, 'Dam!  
I clearly perceive that I am  
A creature that moves  
In predestined grooves  
I'm not even a bus—I'm a tram.'"

I do not believe that man is thus a helpless mechanism. Indeed, isn't the thing that evolution has been working for from the beginning the achievement of that measure of liberty that enables a man intelligently to take charge of and direct his own life? Matter is predetermined. The planets can be accurately predicted as to their exact place centuries ahead, but just as soon as life emerges, predictability begins to cease. As one of our leading biologists said, "You can take three observations of a comet and three observations of a cat, but it is much safer to tell where the comet will go than which way the cat will jump."

Even with that much life you begin to have difficulty in prediction, and then when at last man comes with his intelligence, with what the psychologists call his modifiable behavior, with that amazing capacity of his, after all the most astonishing thing in the universe, to project purposes ahead and work for them, there you get what a philosophically-minded man calls freedom, which is nothing in the world but the capacity of a man within limits to take intelligent charge of his own life. With that much freedom, religion has its place.

I suppose there is another kind of science that does not leave much room for religion. I think it is pseudo-science, that once upon a time, a long, long time ago, nature produced some germ plasm. Never was such germ plasm since the world began and never will be again. It is Nordic germ plasm. We have got it. Anybody who hasn't it is an inferior race, and we are forever and forever the superior race.

Of course the trouble with that is that it is not science. As one of the leading anthropologists in the United States said the other day, forgetting his scientific caution, "That is pure bunk." For I suspect if you could have taken a believer in hereditary foreordination when he was two years old and lost him by accident in the middle of the African jungle, and had him brought up by an African tribe impinged upon

\*Address given at the dinner by the Medical Society of the State of New York, to Dr. Wendell Christopher Phillips, President of the American Medical Association, on January 27, 1927, in the Hotel Waldorf Astoria, New York.

CHART II The Vitamin B Value of the Banana (Preliminary Tests)

The single lines show the individual gains or losses in weight of white rats in a sixty day period using the daily intake of banana indicated and a basal diet adequate in all known dietary factors except vitamin B. The heavy lines are averages. Since it takes 10 cc. of tomato juice or 6 cc. of milk to produce a 20 gram gain in rats in sixty days under similar conditions it follows that 8 to 10 grams of banana is the equivalent of 10 cc. of tomato juice or 6 cc. of milk as a source of vitamin B.

complete in all factors except A until growth declines and indicates exhaustion of the stored resource, and only then apply the test. The standard in this case is 25 grams gain per rat in 56 days. A modification of this procedure is now a standard U S P method. Chart II shows how this method revealed the richness of banana in vitamin A and permitted quantitative comparisons with other sources as shown in Table II.

TABLE II

RELATIVE VITAMIN A VALUES OF SOME COMMON FOOD-STUFFS

Foodstuffs	Amt nec to produce 25 grms	
	gain in 8 weeks	Relative Value
Standard (Butter)	0.020 grms	1
Spinach	0.018	1.11
Egg yolk	0.020	1
Carrots	0.040	0.5
Bananas	0.500	0.04
Cooked green peas	0.500	0.04
Lettuce	0.600-0.700	0.33-0.28
Apples	2.000	0.001

The development of a means of quantitative assay of vitamin value has been indicated in what has preceded, at least for B and C. It must not however be inferred that these methods are yet rigorously perfected. There are many issues undecided as yet. The diet of Sherman and LaMer for scurvy testing is not necessarily complete in all factors except C, and recent work suggests that a roughage added to this diet would improve it. We also are uncertain as yet as to whether the lack of vitamin D in the A testing basal diet is a limiting factor or not. Obviously too there may exist many other factors as yet undiscovered that will again make revisions necessary.

The present status and our problems are perhaps satisfactorily exposed by this presentation and a better basis for vitamin assay is certainly dawning.

losis germ, or perhaps I would choose the day when Pasteur stood mystified before those cows in southern France and for the first time wondered whether there could be such a thing as immunity, and then the day when with his various ages of cultured bacteria he stood with some dead chickens on one side and some live chickens on the other and realized that he had achieved immunity. Think what an instrument for service has been put into the hands of those who love humanity! I say it with a reverence, the one whom I call Master cured a few people whom you could count upon your finger tips through that amazing mastery of mind over matter. But with such instruments of service as modern science has put into our hands is brought to pass the very thing he said, "Greater things than these shall ye do."

This last year I was in Corinth in Greece. Three thousand children had been brought over after the debacle in Asia Minor, orphans, and put into some Greek army barracks there in old Corinth. No sooner had they gotten there than 1,200 cases of malaria broke out. They sent for a trained nurse from Johns Hopkins who was up in Athens and she came down. Will you in imagination think of all the trouble there must have been with malaria in Corinth for numberless centuries past? Will you imagine all the sacrifices that had been offered on pagan altars there somehow to escape that mysterious and unknown scourge? Will you imagine all the prayers in Christian churches and all the supplications before Allah in the mosques of Islam there that had been offered somehow to escape that dreadful scourge? And now a nurse from Johns Hopkins comes down there, cleans up the whole countryside, makes herself a torture and a pest to all the government authorities until they assist her, will not let a single pool go unwatched, until nobody in Corinth need ever have malaria again. And still some talk about a quarrel between science and religion, but see, see the instrument that a real religion, that loves human service, has handed to it by science. Let me at least take this opportunity for myself and thousands of my brethren to acknowledge our unpayable obligation.

Once more let me express our obligation for some of the intellectual ideals that science has supplied us with. For religion deals with things that are rather nebulous at times, somewhat vague, large philosophies of life where it is easy to content ourselves with approximations, and at times to do wishful thinking and slip over into credulity, and from credulity slide down into

superstition, so that for my part I acknowledge an unqualified debt of gratitude for two ideals of science—honesty and humility.

Honesty, like that of Darwin, who said when he was searching for his hypothesis that he particularly noted down every fact that was against his hypothesis, because he noticed that it was so easy to forget the things that were against the things you wanted to prove, that kind of dealing with facts science stands for. You know our modern religion is unpayable indebted for that, it is getting into our blood. We are increasingly impatient with credulity and desirous to deal with things that are so.

Then humility,—I know oftentimes scientific men are conceived of as proud. I know many great scientists, I have yet to meet a really proud one. They are the humblest lot of men I know in one particular. Huxley said "Sit down before fact as a little child. Give up every preconception and prejudice, and be prepared to follow wherever fact may lead, or you will learn nothing."

Those twin ideals, honesty and humility, in dealing with fact, are the basis of science, and to that contribution religion owes an unpayable indebtedness.

You will let me, then, having expressed on behalf of the profession which I represent our indebtedness to the scientific work which your profession represents, say also that after all science is not enough, for here is the problem, isn't it, that all of us have to deal with today—that science puts into our hands tremendous powers that we may either use or misuse. Scheele in 1774, so my friend at Harvard tells me, discovered chlorin, an unspeakable public benediction which today cleanses annually 5,000,000,000 gallons of the nation's water for drinking purposes, but alas, chlorin which was the basis of the deadliest gas used in the last war.

There you have it. Science gives us chlorin. What shall we do with it? We may make it a saving thing and cleanse the drinking water of a nation, or we may make it a poison gas and slay the best youth of the new generation.

So that when science has done its work, still there is work for men of my profession, with the spirits of men, with the motives that drive them, with the faiths that dominate them, with the outlooks on life that make or mar them, and I am glad to pay my tribute tonight to Dr. Wendell C. Phillips, because he has combined in his life these two attitudes of which I have been speaking—a great man of science, and a great man of religion, too.

by the traditions of African savagery, knowing nothing else but the moulding influences of African custom, if he could have stood outside and looked at himself, he would stop saying heredity is everything and acknowledge that environment is something

But what I want to say tonight is that concerning anything like intelligent science and intelligent religion, let's stop talking about conflict. What I intended to do as a man of religion in the midst of a gathering of scientific men was to say that, in the name of religion, I wish to express gratitude to science. That is a tone of voice I hear all too little.

Let me tonight, as a minister speaking to men of science, say, "We who are trying to fight the battle of religion owe to science an absolutely unpayable debt." First of all for the new view of the universe that you scientists have given us. My friend, Dr. Breasted, the Egyptologist, says that once in Florence he had an awe-inspiring experience because they allowed him and his friend, Dr. Hale, the astronomer, to take from the Florentine museum the very telescope that Galileo had used. They took it up to the height of Fiesole, and on a clear night they looked at the heavens through the very lenses through which Galileo first had seen them. He said that it was an awe-inspiring moment to see the moons of Jupiter through the glass through which man's eye first had perceived them.

Think of the view that has been opened to our eyes since that day. Once it was possible to be a polytheist, you can't be a polytheist now. Whatever else may be true about this cosmos, it is unified until, as John Fisk used to say, "Every wind that sweeps the blazes of the sun sways every compass needle in every box on earth." Indeed, I am not so sure that that feat of Copernicus and Galileo was much more wonderful than the feat of that old Dutch janitor whose almost unpronounceable name, Leeuwenhoek, so few people know, that man who experimented with lenses and who first put them together into a crude microscope and saw those strange animals that swam about in a drop of water. We know about Copernicus. Who knows about Leeuwenhoek? And yet there was a discoverer of an infinitesimal world as marvelous as the infinite world of the astronomers, but one world unified, law-abiding before which every intelligent man stands in reverence, and before the infinite intelligence and power that created it I think every thoughtful soul will stand in awe. As a man of religion, I acknowledge tonight to you men of science our unpayable debt for this vastly greater, more awe-inspiring outlook upon the universe that science has given.

In the second place we men of religion owe to the men of science a debt for the instruments

of service that have been put into our hand. One thinks, for example, of the dream that all men of high religion have had for centuries that some day we should have a human brotherhood here, that having made the world in the nineteenth century into a neighborhood, we might somehow now make it into a brotherhood. But what has made possible the feasibility of that dream? Well, of course, it is modern science, it is railroads, it is telephones, it is telegraph, it is radio, it is steamships, it is the things that in spite of ourselves are making us live with ourselves and with each other. One thinks about it as illustrated in the history of our own country. When the United States was thirteen original colonies down the Atlantic seaboard, Thomas Jefferson said he hoped we would not have anything more to do with England than we had to do with China, which shows how little he knew what the world was coming to. We began saying away back there, "No entangling alliances."

Then after the Revolutionary War we stepped back to the Mississippi and we took Texas from Mexico with the aid of the Texans, and we got California by purchase, and Oregon by discovery, until we stretched 3,000 miles from sea to sea, and still we said "No entangling alliances."

Then in 1868 we purchased Alaska from Russia until with our finger tips we touched Asia, and still we said "No entangling alliances."

In 1898 we got the Philippines and became a first-class Asiatic power, took Porto Rico and laid a fatherly hand on Cuba and got Panama and became a first-class South American power, until the sun never sets on our possessions either, and still we said "No entangling alliances."

All the while we were saying this, something else was going on, steamships and railroads and telegraph and telephone and radio, doing the whole world up into one bundle, so that what happens anywhere happens everywhere, and the roofs of Buddhist pagodas shine with the corrugated tin of Standard Oil cans, and still we say "No entangling alliances." You see the theory doesn't fit the facts, because in spite of ourselves we have to get into this international problem science is making for us. Some call it idealism. They say it is visionary. Rather, it is science that is putting into our hands these instruments that force the whole world to live together, so that when a Christian, for example, dreams his dream of something like a peaceful world brotherhood, he owes an unpayable debt to science for the possibilities that he would better acknowledge.

Of course, one illustration of this, perhaps the most beautiful illustration of it, lies in the realm where you gentlemen work. There are a few places in history where a man wishes he might have been—that day, for example, when Koch succeeded first in isolating the tubercu-

considering the fact that the very patients portrayed have almost all passed from view either by reason of cure, removal, or demise

Aside from the immense economy of time and effort, the particular features by reason of which the employment of motion picture film is most especially adapted to the teaching of medical subjects, are its ready accessibility and its permanency of form. To this we may add the fact that it is a practically indestructible record which may be used time and time again without any more exertion than the printing of new positives from the original negatives. Availability is a very important feature in the teaching of medical subjects. For instance, a physician recently dropped into our clinic at the Bellevue Medical College and said that he was particularly interested in a certain rare form of rectal disease and wanted to see whatever could be seen on that subject. As it happened, the condition was of such rarity that there were no cases in the hospital at that particular time and for that matter had not been for over a year. Yet by the simple process of the motion picture film, this man was able to view over twenty such cases in a short period of time. When I tell you that these constituted all the cases that had come into a hospital for some eleven years past, you will readily realize the important rôle that the motion picture film plays or can play in keeping striking clinical cases indefinitely on ice.

The clearness and simplicity of the motion picture portrayal of a clinical condition stands in direct contrast to the totally inadequate view that a medical student can obtain from a seat in the amphitheatre. Those who have been in the

amphitheatre of an operating room will recall how the students and physicians are seated row upon row in a semicircular manner on benches whose distance range from twenty to fifty feet from the field under observation. When you consider that such field is at best six to eight inches square and that even this is encroached upon by operating hands and instruments, you can well imagine that the actual view possible is very small indeed. Contrast this with the fact that an operative wound photographed and thrown upon the screen shows an area six by nine feet instantly visible to everybody and so complete in its clearness and abundant in its detail that accurate observation cannot be avoided.

We have noted so far the great economy in time and effort obtainable by putting medical educational facts into motion pictures, and furthermore have dwelt upon the superiority of such a record from the standpoint of ready availability and repeatability, but perhaps the most important virtue in the method lies in that extensive flexibility which permits constant additions, corrections, or subtractions, and which makes it possible to keep the record constantly up to date and complete to the utmost. Moreover, the same flexibility permits the rearrangement of material assembled so that it may be correlated along the lines of a logical presentation of the facts on each and every medical subject.

Experience with our motion pictures in the classroom has abundantly demonstrated their pedagogic value, and points the way to the establishment of similar courses in all the specialties. In the language of the day "*It won't be long now!*"

## FETAL AND NEO-NATAL MORTALITY\*

By MEYER ROSENSOHN, M.D., NEW YORK, N. Y.

**T**HIS paper is based on a study of the work at the New York Lying-in Hospital for the two years 1924 and 1925, and represents an indoor and an outdoor service, the former about twice as great numerically as the latter. In neither service do the hospital rules permit any operation of any kind except in the presence of a member of the attending staff, unless it be in the face of a grave emergency.

As a preliminary, it may be wise to refer to a few fundamental considerations. First, the term still-birth has been applied to every case where a recognizable embryo or fetus is obtained, irrespective of the period of gestation. Secondly, a still-birth differs from a death only

in the absence of respiratory movement, thus, even if the heart beat for an hour or more after delivery, a still-birth has occurred if no attempt at breathing has taken place. On the other hand, should there have been a brief respiratory effort, then a death has taken place one minute or more after birth. Thirdly, the term premature and its application are very hard to limit. Arbitrarily, it has, in this paper, been applied to all cases where the weight is 1500 grams or less, but its actual definition is still being considered by a committee of several of the maternity hospitals.

With these considerations in mind there were for the past two years in the Lying-in Hospital a total of 10,720 confinements, with 10,829 babies. Among these there were 460 still-births and 277 infant deaths as shown in Table I.

# A ONE YEAR'S REPORT ON THE SUCCESSFUL EMPLOYMENT OF MOTION PICTURES IN MEDICAL EDUCATION

By J F MONTAGUE, M.D., F.A.C.S., NEW YORK, N Y

From the Rectal Clinic, University & Bellevue Hospital Medical College.

**T**HERE is much discussion abroad at the present time as to the possible value of the motion pictures as a medium of instruction in medical colleges. It may, therefore, be of value to those contemplating the employment of this method to hear the report of one who has successfully used this method for over a year.

In 1925 we completed the construction of a series of motion pictures dealing with rectal diseases and their treatment. This series was built up from motion pictures of actual cases which had come under our observation over a period of eleven years at Bellevue Hospital and the University and Bellevue Hospital Medical College. While the presentation of an eleven year clinic such as this collection of pictures represents would undoubtedly have been of interest to anyone studying rectal diseases, yet the fact remained that, although the material was all there, it needed editorial arrangement in precisely the same manner that the strips of film which represent the individual scenes of a motion picture story require much cutting and editing before they are finally offered to the public. The obvious step to be taken, therefore, was to group these various motion picture "shots" according to the disease they portrayed, and then to title them with descriptive matter. This was done, and when viewed they presented an interesting spectacle.

It was quite evident, however, that there was something lacking in the structure we were trying to build. Upon analyzing the situation we concluded that, although it was all very well to show a series of diseased conditions such as was mentioned, yet from the standpoint of the student, treatment was the question paramount in his mind. Accordingly, we proceeded to make motion pictures of all the surgical operations which rectal surgeons employ, such as hemorrhoidectomy, fistula operation, etc., as well as the various medical treatments, such as injection treatment of hemorrhoids and the non-surgical treatment of rectal stricture. When this immense amount of material had been accumulated, we naturally thought that our labors would be over and that we could settle down to the practical employment in teaching what had taken so much time and effort to gather. However, although the surgical operations or medical treatments were perfectly and clearly shown and in a manner far superior to what could be possibly viewed by a student observer at a clinic, yet the fact remained that the mind seemed to be looking for some additional help in understanding the exact process of the technique. The answer to this was found in the employment of animated cartoons or dia-

grams. By preceding an actual showing of the surgical operations with an animated diagram of what was to take place, the ideal appears to have been found.

At the present time our entire series of films aggregate about 55,000 feet constituting a thoroughly organized and correlated fund of knowledge on the subject of rectal diseases which is made easily and instantly available to any medical student. Instead of being under the necessity, as heretofore, of lumbering from one clinic to another seeing the cases that *happen* to come in, and in the meantime obtaining a very haphazard impression of widely varying clinical conditions, the student may now make an intensive and thorough study of each subject in the field of rectal diseases. Not only may he see the actual conditions, but he may also see the same case operated upon, dressed from day to day, and finally see the completely cured case, all in the brief time required to show the motion pictures. Could there be any more complete follow-up system?

We have also succeeded in taking motion pictures of the interior of certain portions of the intestinal tract. While X-ray pictures are only shadows cast by opaque material in the intestine, the new motion pictures actually show the inside of the intestine. This has never been done heretofore, and furnishes the medical profession with a new means of observing the intestines, both in health and disease.

The dissection of an entire human body—a tedious process taking months of careful work—is shown in faithful detail in our motion pictures in a little over an hour. Moreover, without the necessity of again going through the dissection the process may be repeatedly shown until the student is entirely familiar with its detail. In this way, from the seat of a comfortable chair in the lecture hall he may learn what otherwise would require months of messy work on a malodorous cadaver. Thus, through the agency of motion pictures, the anatomy and physiology of the body in health, the characteristic appearance of cases of disease, and each step in the plan of its treatment may be presented.

If a student is slow to grasp, the pictures may be run twice or more times. If an interesting phase is observed, the picture may be stopped and started again as soon as it has been sufficiently observed. Finally, in this series of pictures there are to be observed all the interesting intestinal and rectal cases that have come through Bellevue Hospital in the last nine years. Where else can a nine year clinic such as this be viewed in a little over an hour? This is all the more remarkable

among 10,720 confinements, representing 3.4%

In these full term babies, a study of the causes is of interest and is shown in the following table in which the effort has been made to distinguish between the operative and spontaneous deliveries

TABLE VI  
*The Full Term Baby*

	Still-birth	Death	Total
Operative delivery	126	56	182
Spontaneous delivery	61	118	179
Total	187	174	361

TABLE VII

	Operative	Spontaneous
	182	179
Atalectasis & Asphyxia	66	55
Cerebral hemorrhage	58	35
Fracture or separation of vertebrae	11	4
Craniotomy	16	
Anomalies	8	21
Inanition		7
Pneumonia	1	12
Hemorrhagic disease	2	10
Lues	1	5
Other causes	21	30

The occurrence of cerebral hemorrhage in almost one-third of the operative and in one-fifth of the spontaneous deliveries is noteworthy, in addition to this is the incidence of congenital malformations, these were practically all incompatible with life, eight of them were among the operative, and twenty-one among the spontaneous deliveries

Referring further to these congenital conditions, in most of which autopsies were performed, Table VIII is of interest

A further reference to Table VII shows that in sixteen of the full term cases craniotomy was done, as regards this operation Table IX is noteworthy

In the instances of the four premature babies there existed in the mothers, in two cases placenta praevia, in one pyonephrosis and in one toxemia. Among the full term cases, in one congenital lues was present with gummata of the liver and lungs, the operation was performed seven times in primiparae and seven times in multiparae, there was a big baby in eight cases and an abnormal pelvis in five. They represent cases where an error of judgment led to the necessity for the operation

Again, elaborating Table VII with reference to the operative deliveries, Table X and XI give the details in the Cesarean and the high forceps cases

TABLE VIII

	Death		Still-birth		Total	
	Full Term	Pre mature	Mac erate	Full Term	Pre mature	
Anencephaly	1		1	5	5	12
Monstrosity	1			1		2
Congenital heart	5					5
Umbilical hernia	3					3
Hydrocephalus			1			1
Hydrocephalus & spina bifida	2	1			1	4
Eventration	1					1
Stricture oesophagus	1					1
Absence intestine	3					3
Diaphragmatic hernia	1					1
Congenital adhesions & perforation caecum	1					1
Fetal anasarca	1				1	2
Cleft palate, hare lip & eye defect	1					1
Congenital, absence bile duct	1					1
Cleft palate, atrophy thymus	1					1
Total	23	1	2	6	7	39

TABLE IX  
*Craniotomy Cases*

	Full term	Premature	Macerated
Craniotomy	8	2	
Perforation of after coming head	6	2	2

TABLE X  
*Cesarean Cases*

	Total	Pyelitis	Cardiac	Placenta praevia	Acid Hemorr	Rupt'd Uterus	Tox Eclam	Contr Pelvis
<i>Still-births</i>								
Full term	11				2	3	2	4
Premature	6			1	2		1	2
<i>Macerated Deaths</i>								
Full term	6				1		1	4
Premature	5	1	1	1			2	..

TABLE I

	1924	1925	Total	Per- cent	Rate per 1000
Labors	5,457	5,263	10,720		
Babies	5,508	5,321	10,829		
Still-births	227	233	460	4.2	42.5
Deaths	152	125	277	2.5	25.6

In all of these 737 still-births and deaths there were 346 autopsies

To consider the still-births first, they fall naturally into three headings the macerated, the premature and the full term, and are noted in Table II

TABLE II

	No of cases	Percentage of total confinements
Macerated	185	17
Premature	88	0.8
Full term operative delivery	126	1.1
Full term spontaneous delivery	61	0.5
Total still-births	460	4.2

From this table it is seen that 185 cases were encountered where the fetus was already macerated, stated otherwise, it becomes apparent that of 460 still-births, 40% have been dead in utero for some time. It is not here the object to discuss the time of occurrence of maceration in reference to the onset or progress of labor.

Among these macerated fetuses the question of the presence or absence of lues is important and is shown in Table III, here, as well as in the succeeding table, for comparison, the two years 1924 and 1925 have been separately quoted.

TABLE III

	1924	1925	Total	%
Positive Wassermann in Mother	15	14	29	15
Negative Wassermann in Mother	60	69	129	70
No Wassermann taken	19	8	27	15
Total	94	91	185	—

It is astonishing and certainly will bear a moment's consideration to see how exactly the two years compare in incidence, and in reactions. The greater frequency in the 1925 figures is at the expense of cases where in the preceding year no Wassermann was taken. The total of 91 for 1925 as compared with the total of 94 for 1924, is undoubtedly due to the fact that in the past year we had 194 less cases. It is thus to be noted that in 129 of the 185 cases or in 70% of the macerated fetuses there was neither clinical nor

laboratory evidence of lues in the mother nor was there any evidence in the still-born fetus at the post-mortem examination.

If the figures are studied with a view to etiological factors, definite causes were found in 46 cases, excluding, of course, the 29 positive luetics. This is shown in Table IV.

TABLE IV

	1924	1925	Total
Toxaemia and eclampsia	13	7	20
Previous still-births	5		5
Diabetes	4		4
Trauma	2	1	3
Tight cord	3		3
Placenta praevia	2	1	3
Monster	2		2
Pyelitis	1		1
Premature separ. placenta	1	1	2
Fibroid uterus	1		1
General peritonitis in mother	1		1
Dry labor		1	1
No cause	44	66	110

As was stated above, Table II, the prematures among the still-births numbered 88, and included all embryos and fetuses under 1,500 grams. Most of these were in cases which could be called abortions of three to five months, but there were five cases of anencephaly and one of spina bifida with hydrocephalus. These are referred to in one of the succeeding tables dealing with congenital defects.

In considering the neo-natal deaths all cases were included where the child breathed and where death occurred either immediately or at any time during the hospital stay. Under ordinary circumstances, because of the requirements of the service patients are discharged on the tenth day after delivery but where any untoward conditions arise, the hospital stay is prolonged for weeks and even for months. For a better understanding these neo-natal deaths are subdivided as to pre-maturity or full term and are shown in the following table.

TABLE V

	Total	10,720	%
Labors	"	103	0.9
Premature	"	174	1.5
Full term	"	56	0.5
Operative delivery	"	118	1.0
Spontaneous	"		
Total		277	2.5

Disregarding the prematures in this table and in Table II, we have for consideration the full term baby and the method of delivery as shown in Table VI.

As might be expected there is a greater incidence of still-births among the operative cases and a greater number of deaths among the spontaneous deliveries. These figures show a total of 361 full term still-births and neo-natal deaths

TABLE XVI

Total full term

version	13	52	8	11	307	65	35	22

The figures which have been quoted and the tables which have been outlined indicate a still-birth rate of 4.2% or 42.5 per 1,000, and a neonatal death rate of 2.5% or 25.6 per 1,000. For the City of New York in 1924, in 136,884 births, there were 4.7% still-births and 3.2% neo-natal deaths and for 1925 in 134,924 births, there were 4.5% still-births and 3.1% neo-natal deaths. A study of these figures and a comparison with published records referred to in another article leaves one with a sense of discouragement. The figures are too high. It is true that where the mother comes to us with a fetus in utero already dead for some time there is no discredit to be assumed from the still-birth.

In the light of our present knowledge it is not possible to eliminate the congenital defects. Yet, a great deal can be done toward watching and

educating the prospective mother so that her baby will not be born or die prematurely, toward instructing her as to proper care and hygiene of pregnancy in order that she should not develop eclampsia or intense toxemia. It is here that preventive medicine and prenatal care can conserve the life of the baby and in a measure eliminate the macerated fetus, it is here that we can reduce appreciably the mortality of childbirth. It is only by such measures that there is any hope of cutting down the high figures and this should be the aim of the attending physician. The greatest judgment should be exercised to avoid the necessity for a craniotomy, one should be influenced oftener to interference, and this should be instituted earlier and by the abdominal route where non-engagement or lack of progress indicates some abnormality.

## THE SYMPTOMS AND TREATMENT OF UNCOMPLICATED DISPLACEMENTS OF THE UTERUS\*

By P BROOKE BLAND, M D., PHILADELPHIA, PA.

From the Department of Obstetrics, Jefferson Medical College.

### INTRODUCTION

IN prefacing my remarks, I wish to say that this is the second paper I have recently prepared and presented on the conservative treatment of uncomplicated displacements of the uterus.

The first paper was read at a meeting of the Brooklyn Gynecological Society on Feb 5, 1926.

The text of this contribution is largely a reiteration combined with certain additions of statements made in my previous paper.

My reason for once more contributing a paper on the subject is based on the conviction, now more firmly founded than ever, that most patients with simple displacements seem to survive comfortably without operation or any other form of radical treatment.

In considering in detail the topic embodied in the title of this paper, I have deviated somewhat from the path customarily followed and have included not only the treatment of simple uncomplicated displacements of the uterus, but certain other phases of these conditions as well. This plan unfortunately prolongs my prefatory remarks, but it is justified on the ground that they embrace certain features of the problem which I believe are more important than the treatment of a displacement itself.

It is obvious to all that within the past ten years all departments of scientific endeavor have made remarkable progress and it is equally obvious to all that the science of medicine has kept quite abreast of scientific progress in general. Specialization has played a definite influential role in this period of evolution, but specialization, while prominently displaying an embellished

\* Read at a meeting of the Buffalo Academy of Medicine, May 20, 1926.

As an explanation of this table it should be said that the macerated baby in one case was one of twins in which the second baby was alive. The other was a case of accidental hemorrhage in a toxæmic mother. Among the cases of contracted pelvis, broncho-pneumonia and erysipelas caused the death on the twelfth day of one baby, in another baby perforation of the caecum on the second day caused death.

In one of the prematures, the operation was a post-mortem Cesarean, in a case of salvarsan toxæmia, while, in another an anencephalic monster was obtained.

TABLE XI  
*High Forceps Cases*

	Total	Atalect asphyxia	Cerebral Hemorrhage	Fract. skull
<i>Still-births</i>				
Full term	9	2	6	1
Premature				
Macerated	2			
<i>Deaths</i>				
Full term	4	1	3	
Premature				

The high forceps operation was done in five cases for fetal distress, in five cases for abnormal pelvis, and once each where a prolapsed cord, an occiput posterior position, and a tonic uterus were present. The incident of cerebral hemorrhage in this type of operation is what might be expected of such a difficult procedure.

A table worthy of study is that referred to below dealing with the breech.

TABLE XII  
*The Breech Deliveries*

Total labors	10,720	Incidence	1 in	%
T'tl no breeches	286		38	2.6
	Still births	Deaths	Total	%
Full term	26	18	44	15
Premature	10	12	22	7.7
Macerated	28		28	9.8
Total	64	30	94	

It is seen from these figures that among 286 breech cases, there were 94 deaths and still-births. About one-third of these had been dead in utero for some time and were macerated on delivery, about one-fourth weighed less than 1,500 grams and can properly be considered non-viable. The remaining 44 cases represented the mortality for the full term breech. The causes of death in these cases is noted in Table XIII.

In the effort to ascertain the mortality for the breech, we are justified in excluding the six congenital anomalies, one case of asphyxia, brought in dead (not a still birth), the case of pneumonia at fifteen days and the case of malnutrition which had been discharged and returned to the hospital after three weeks. This leaves

TABLE XIII

Anencephaly	3
Hydrocephalus and spinabifida	1
Separation or frac- ture vertebrae	5
Asphyxia	.17 and 1 brought in dead.
Cerebral hemor- rhage	12
Hemorrhagic dis- ease	1
Other congenital defects	2
Pneumonia	.... 1 at 15 days
Malnutrition	1 disch. and returned after 3 weeks.

thirty-five full term babies among breech deliveries, a mortality of 12%.

Finally, the figures dealing with our cases where the operation of internal podalic version was resorted to is given in Table XIV and Table XV. The operation was performed 307 times, the indications are outlined for the full term fetus only.

TABLE XIV  
*Internal Podalic Version*

	Deaths Full Term	Pre- ma- ture	Full Term	Still-births Pre- ma- ture	Macer- ated
Cerebral hemorrhage	6		14		
Atalectasis and asphyxia	5		27		
Fracture or dislocation vertebrae	2		5		
Craniotomy			6		
Total	13	8	52	11	11

TABLE XV  
*Indications for Internal Podalic Version*

	Full term	Death	Still birth

Toxaemia			2
Twin and triplet.		1	1
Monstrosity		1	1
Prolapse cord			8
Accidental hemorrhage		1	1
Abnormal pelvis			14
Inertia, big baby		5	13
Malpresentation		4	7

Taking into consideration the figures indicated in the previous records and noting in the succeeding table the corresponding figures, we have a statement of the full term obstetric mortality with the deductible cases excluded.

In this connection to state differently the figures noted in the preceding tabulations, the following table gains added interest and indicates the mortality for the more common conditions and procedures met with in obstetrics.

dren The organ generally is in constant retro-position and in nearly all instances, owing to hyperplastic alteration of its walls, it frankly enlarged. The increased weight of the structure combined with the intra-abdominal pressure may imprison it in the hollow of the sacrum or it may be thus fixed as a result of peri uterine infection. The condition usually is a sequel of parturition, so the displacement itself in most cases is associated with parturitional injury. A complicated displacement is one associated with definite pathologic alteration in the uterus itself, in the circumjacent structures or in both.

There is still another form of posterior displacement deserving mention. I refer to those cases so commonly found in the highly neurotic, operatively over fed, sanatoria domesticated women or in other words, the physically incompetent woman.

The number of this variety operated upon is beyond computation. Have many, if any, ever been benefited? It is obvious that displaced uteri arising in patients of this so-called neurasthenic group are in no sense pathologic in themselves, but rather a manifestation of the general passive or subnormal condition of the patient herself.

**Symptoms**—Probably no conditions arising in the human body have been so falsely accused of creating symptoms, both systemic and local, as innocent—not pathologic—uterine displacements. For no other disturbances have such an array of therapeutic methods, both medical and surgical, been designed with almost equal uniform failure in affording symptomatic relief.

Normally, the uterine body is a freely movable organ and so long as it is normal in size and freely movable, may it not be from a physiologic, as well as from an anatomic standpoint, as normal posteriorly as anteriorly?

The teaching that the uterus is maintained in position by a combination of the pelvic ligaments, it seems to me, is not physically nor anatomically true. Except during pregnancy, the pelvic ligaments do not act as stays or supports, as we have been so long taught. Personally, I have never observed, save during pregnancy, the round and associated ligaments, especially the round ligaments, to act other than in a simple passive capacity. Fothergill states, "Though all the ligamentous structures attached to the uterus, except the cervico-pelvic-muscle bands, be severed, the organ will remain in the so-called normal position."

The round ligaments usually are observed as two cylindric or ribbon-like cords passively traversing the sides of the pelvis from the internal abdominal rings to the uterine cornuae. Rarely are they seen in a state to imply that they in any way act as a sustaining force of the uterus.

It is commonly assumed that a great variety of symptoms may be caused by simple displace-

ments, but it is clear that the mere association of symptoms cannot be explained either on anatomic or pathologic grounds, for simple displacements in themselves are not pathologic. Unless the displacement be frankly complicated it cannot excite symptoms, phenomena, we are taught, always indicative of deranged function or altered structure. I am persuaded that most observing men today are convinced that uncomplicated displacements are incapable of provoking symptoms. If one could accept the hypothesis that a simple displacement of the uterus inhibits the supreme function of the organ, namely, child-bearing, then one might assume that our Creator adopted this as one of the chief methods of exterminating the human race.

Except in very rare instances, an uncomplicated displacement can not possibly interfere with conception or any other function. If this were the common source of female sterility, the condition would be infinitely more frequent than it is, since it may not be far of the mark to say that twenty-five per cent or more, women of the child-bearing age could be included in this class.

Personally, I am familiar with no data which prove that simple displacements bear an etiologic relationship to sterility. In all our literature reference is made to this subject, but there are no data on which one can base positive conclusions. Sterility is often cited as a sequel of displacements, but rarely is the story fully told. There is a vast difference between a one year, two-year, three- and five-year sterility. Simple displacements, I am convinced, play but a minor role in the barrenness of women.

While sterility is usually set forth as one of the symptoms of malposed uteri in one paragraph, the paradox of the possibility of abortion taking place is mentioned in the next.

That this unfortunate termination of pregnancy may take place in uteri imprisoned underneath the sacral promontory no one will deny, but pelvic incarceration of a gravid uterus is an exceedingly infrequent occurrence. In an experience extending over a period of several years, I have not observed this combination of events.

With regard to the teaching, more or less prevalent, that a simple retrodisplacement may jeopardize the fate of the embryo if pregnancy should occur, by expelling it prematurely, is, I am convinced, a species of gynecologic pedagogy, not wholly true. Occasionally abortion may occur, just as it does occur occasionally under entirely normal circumstances, but that it is a common cause of abortion, I regard as exceedingly doubtful.

Impaction with abortion as a sequel is possible, but how often has it been observed? The "danger" to a pregnancy complicating a simple retrodisplacement is over emphasized, if not in some instances made a bugaboo. In this con-

side of beneficence, at first, unfortunately, exposed a drab side of passionate radicalism. This vicious feature of specialization, thanks to a sound philosophy, has gradually been settling toward a rational conservatism.

The specialty devoted to the diseases peculiar to women, has contributed, on the whole, a gratifying quota and while there is still much to be desired from the conservatism aspect, gynecology no longer can be, as formerly, regarded as ultra radical.

The conservative wave, starting as a faint, but promising ripple, about twenty-five years ago, has gradually expanded into a billow of some magnitude and the crest of the wave is not yet in sight.

It is destined to broaden and ultimately will embrace certain pelvic conditions which are still looked upon as surgical.

It would be a sad commentary to accuse our eminent predecessors of lack of knowledge with respect to the fundamental importance of conservative work in dealing with organs first of vital systemic value and second of transcendent importance in propagating the human family. Yet the former custom of indiscriminate and oftentimes sacrificial surgery is wholly beyond the comprehension of men active in gynecology today. I am sure all agree that in no department of medicine is conservative effort more essential than in gynecology, a specialty dealing with organ fundamentally concerned in initiating and maintaining the phenomena involved in the reproduction of life.

Within the past decade certain diseases of the generative organs, heretofore regarded as wholly surgical, have fallen in the category of medical or at least semi medical conditions. In this list may be included, for example, the acute pelvic infections, infected abortions, simple uterine displacements, uterine myomas and uterine cancer, especially cancer involving the cervix. Formerly, to all the diseases enumerated, surgical therapy was almost routinely applied.

During the past ten years, progress along the lines of conservation has been almost beyond belief and it seems quite safe to say that operatively gynecology has decreased twenty-five per cent or more.

While I realize it may not be prudent to deal in prophecy, I believe the next ten years will see the conservative pendulum swing still farther, so much so that gynecology may not be the alluring surgical specialty it has been in the past.

Indeed, it is possible that only a few pelvic disorders will be looked upon as truly surgical, such, for instance, as pathologic uterine displacements, partial or complete uterine prolapse, ovarian neoplasms, gross parturitional damage, frank pus collections and large uterine tumors.

It is not beyond hope that even certain of the conditions named, especially uterine growths, will require surgery, since by early recognition and prompt irradiation they will be destroyed before attaining surgical proportions. Gross obstetric lesions will I believe, largely be prevented by the adoption and practice of ante natal care—the strategy of obstetrics, as well as discriminating and more skilful obstetric tactics—intranatal work—a consummation devoutly to be wished.

It is not my purpose to portray in golden hues, a picture of the futurist type, but I am persuaded that the final picture will be more richly tinted than even it is today. I do not wish to imply that we shall ever reach the blissful millennium, but I do wish to imply that unless we progress and unless our methods change for the better, as they have in the past, and as they inevitably must in the future, we will fall far short of fulfilling our destiny.

Like all specialties, gynecology is not guiltless of sins of omission, and, especially, sins of commission. As a specialty, it has largely traversed its dark pathway of ruthless surgery and, though there are still murky bogs calling for attention, its gloomy chapter of ultra radicalism has been forever sealed.

Among the pelvic conditions which have presented a comely figure to the practicing gynecologist, a group which developed an early and abiding infatuation and a group to which assiduous court has long been paid was uterine displacements. Indeed, of the manifold disorders arising in the female pelvis, none have presented a more alluring physiognomy than malpositions of the womb.

Since the discussion of the title of my paper is governed by the qualifying term "Uncomplicated" it seems proper that my interpretation of the phrase be explained.

There should be no serious difficulty, if difficulty at all, in defining and recognizing either a simple or a complicated uterine displacement.

Each type has characteristic features of distinction. I think most men would regard an ante or retroposed uterus of relatively normal size, freely movable and occurring in young single women or young parous married women as one of the uncomplicated variety.

I am equally sure that most observers would also regard a uterus of normal size, one not constantly anterior or posterior, arising in the type of patients to whom reference has just been made, as truly uncomplicated.

As regards the complicated or pathologic retro displacement, for instance, there are no barriers of obscurity offered to its recognition. Its features, too, are plain.

It is rarely found in young single women or young married women who have not borne chil-

uteri produce no symptoms and that operative procedures on such cases must emphatically be condemned

The retroversion question has also been most clearly set forth by Jaschke. In a study of 1,000 cases of retroposition, compared with 1,000 cases of ante-position, this observer found that the supposed characteristic symptoms of retroposition, menorrhagia, leukorrhea, dysmenorrhea, constipation, bladder irritation, backache and sterility occurred just as often in the anterior as they did in the posterior position.

Jaschke has reached the conclusion, therefore, that an uncomplicated retroposed, movable uterus causes no characteristic symptoms of any kind and no characteristic distress.

Many other writers of wide repute have contributed to this phase of the matter and I shall at this time present their views.

Leda J. Stacy says on the whole there seems to be little difference in the character of the symptoms in ante-position and retroposition.

Palmer Findley states the popular idea, once held, "that uncomplicated retrodisplacements of the uterus result in congestion and excite local symptoms, as leukorrhea, dysmenorrhea, and menorrhagia, is not justified in fact."

J. Wesley Bovee says, "I am convinced that uncomplicated uterine retroversion has no symptoms."

J. M. Baldy, as early as 1915, said, "Ninety-ninths of the operations performed on women for retrodisplacement are uncalled for and that the number of retrodisplacement operations is limited only by the number of females in existence."

J. F. McGrath supports the views expressed by the men just mentioned, especially as regards the so-called congenital type of retrodisplacement.

Realizing that my paper is dedicated to an analysis of uncomplicated displacements of the uterus, it may not be regarded as apropos to even mention that insignificant entity, if really an entity at all, ante displacement. It would be a fatuous waste, indeed, of priceless time to even attempt to review the multiplicity of symptoms and the mammoth therapeutic pyramid erected to the glorification of this pigmy of gynecologic deities.

In the not far distant past no gynecologist, "high though his titles, proud his name, boundless his fame as wish could claim," was too great to do obeisance to this mythical goddess.

Personally, I do not believe a simple ante displacement, one regarded as beyond the so-called natural ante flexion, is capable of exciting symptoms.

A pin hole as I have never seen or have I ever observed a cervical canal with a diameter less than the diameter of a red or white blood cell, the channel through which the menstrual fluid makes its exit from the uterine cavity.

Menstrual symptoms associated with ante position must, therefore, be looked for in structures other than the uterine body.

The train of symptoms often ascribed to an acutely ante flexed uterus is most frequently associated with the type of organ classified as the infantile variety. This is most commonly observed in individuals who present anything but infantile characteristics. These patients, on the contrary, are, in the main, of the gigantic type. This feature in itself clearly indicates that the source of the trouble is not in the uterus, but in some derangement of the endocrine system. Herein lies the origin not only of the maldeveloped uterus, but the dysfunction, expressed symptomatically in dysmenorrhea, partial or absolute amenorrhea and sterility, as well. The bearded face, masculinity, moderate or mammoth body development combined with an ante posed ill developed uterus, form a symptom and sign complex which speaks with plain intelligence of the fountain head of the trouble.

It is a common observation that the bigger the patient the smaller the uterus and the more profound the functional derangement.

*Treatment*—I have devoted considerable time to the general discussion and symptomatology of simple displacements. I adopted this course because I believe the study of these phases of the subject are more important than the treatment of the displacement itself.

In considering the therapy of simple displacements, while it may shelter one from argument, if not criticism, by assuming a compromising middle course, I shall steer clear of compromise, because I believe, except in very rare instances, *simple displacements of the uterus are not worth treating*. As Goldsmith said of Burke "I select this course not because it is expedient, but because I regard it as right."

The operative treatment of uterine displacements, starting in the large medical centers about thirty years ago was grasped with avidity throughout the country. In the rural communities, however, surgical measures, as one would naturally expect, required time for familiarization and adoption.

In the metropolitan districts after a trial of more than fifteen years, it was found that surgery did not provide symptomatic relief, that in most instances the work was futile and disappointing, if not in many cases even dangerous and harmful.

It was further found, finally, that the long chain of symptoms ascribed to simple displacements could not be substantiated by experience, and now the numerous operations described for the trouble are gradually being abandoned.

Since it required a season of time to popularize surgery with the view of correcting displacements, so it will require some years to

nection, I hesitate to use the word "coercion," but I do know the term in the form of a method is sometimes employed in impressing a patient with the "seriousness" of the trouble and I regret to say it also occasionally is used in equally impressing a patient with the "necessity" of surgical interference.

The magnitude of the symptom complex, so frequently ascribed to displacements of the uterus, to me, seems incredulous and can not be explained on rational grounds.

Indeed, nearly every conceivable symptom, as nervousness, functional and even organic, sterility, leukorrhea, disturbed menstruation, dyspareunia, irritation of the bladder and bowel and, of course, the Nemesis of all women—backache—is often attributed to simple uterine displacements.

Backache, especially, is the most popular selection, but this symptom, it has been said, may be caused by anything from the common drama of domestic life—"the family quarrel"—to uterine carcinoma.

Chipman quotes LaRoche-faucold, who said "Pain is the greatest liar in the world," and Chipman goes farther, asserting, that of the painful liars extant, "backache is the greatest Ananias or—Sapphira—of all."

One may still find a few men incredibly teaching and some patients credulously believing that backache may be caused by "the uterus attaching itself to the spine."

Could any teaching be more fallacious?

But La Fontaine enunciated the aphorism "We believe easily what we fear or what we desire."

The men propounding this thread-bare doctrine ostensibly believe with the ancients that the uterus has the unusual facility of sailing about like a rudderless ship, ultimately anchoring itself to some favored section of the body. To these gentlemen, globus hystericus is still a regal entity.

I do not know whether you encounter this special guild of chicanery in this section of our country, but I do know it prevails in the vicinity of the City of Brotherly Love.

Indeed, this malicious teaching, I am confident, is not limited to the small section of the country to which I have referred, but it is, I believe, more or less prevalent in most of the area covered by the path of the sun from its awakening in the Atlantic to its final repose in the Pacific.

The teaching is utterly false and the party to benefit thereby is obviously not the patient, but the individual who unscrupulously lends himself to such an iniquitous system of medical banditry—a system which

"May have Heaven in its looks,  
But Hell in its name."

It is taught, too, by men whom I am confident know better, but taught nevertheless, words—words.

"In each of which the teacher shakes a lance,  
Though brandished in the eyes of ignorance."

I am fully conscious of the feeling respecting the current of thought encircling the topic of uterine displacements. I realize, as I am sure you all do, that there is still a wide diversity of opinion concerning all features of the subject.

Unanimity of opinion has not crystalized regarding the symptomatology and treatment of displacements and perhaps it never will. But unanimity of opinion rarely applies to anything and it would be obviously unnatural to expect a unanimous judgment with regard to this phase of gynecology.

In this country two interesting papers recently have appeared, one by Dr. Arthur Dean Bevan—written editorially—if not wholly condemning, advocating at least a reversal of our attitude with respect to both the symptoms and treatment of backward displacements. The other paper, analyzing all features of the trouble and advocating a more compromising attitude, indicates its author, Dr. George Gray Ward, Jr., believes that certain displacements are influential in exciting symptoms and that in these surgery is not only justifiable, but successful.

In England, too, at a recent meeting of the British Medical Association at Bath, a lengthy paper was presented, depicting and ascribing a long chain of symptoms as due to simple backward displacement. In this contribution surgical therapy was strongly advocated, but in the lengthy discussion which followed the contentions of the contributor were not supported. Of the various gentlemen who took part in the discussion, ten in all, a decidedly mellow middle course was advised. In therapy, surgery was given second place.

Bevan in his paper, to which I have already referred, expresses his convictions regarding displacement in the following language:

"Thirty years or more ago, as a young surgeon, I was very skeptical about the local and general symptoms ascribed to retroposition of the uterus. I could not understand how a movable retroposed uterus could excite symptoms any more than a mobile sigmoid which might fall backward or forward or right or left."

"I soon found that patients upon whom I operated and brought the uterus forward in the supposed normal position, were only not benefited, but many were made worse by the operation, so I, therefore, early discarded it as unnecessary and illogical."

Looking upon this problem, he says, as a piece of scientific research, we are in a position today to state that uncomplicated, movable retroposed

to criticise are often least able to appreciate" (Joubert)

Two hundred years ago, Alexander Pope in his Essay on Criticism said

"'Tis hard to say, if greater want of skill  
Appear in writing or in judging ill,  
But, of the two, less dangerous is the offence  
To tire our patience, than mislead our sense  
'Tis with our judgments as our watches, none  
Go just alike, yet each believes his own"

### THE TYPES OF GOITER ENCOUNTERED IN CHILDREN\*

By J WILLIAM HINTON, M D, F A C S, NEW YORK, N Y

CONTRARY to the statements of some authors there are three types of goiter seen during childhood. First, The Goiter of Adolescence. This is a physiological hypertrophy of the gland with the secretory activity usually diminished. Occasionally the secretion is increased. Second, Adenomatous Goiter. This is a pathological hypertrophy and hyperplasia confined to one portion of the gland. The secretory activity may be normal or increased. Third, Exophthalmic Goiter or Graves Disease. This is a pathological hypertrophy and hyperplasia involving the entire gland. The secretory activity of the gland is always increased.

*Adolescent Goiter*—This is the type of goiter most frequently encountered and it constitutes about ninety-five per cent of the goiters in children. It is subdivided into two groups. First. Those with a normal or diminished secretion, which constitutes about ninety-eight per cent of the adolescent type. Second. Those with an increased secretory activity or hyperthyroidism.

*The Signs and Symptoms of Adolescent Goiter Without Hyperthyroidism*—The mother or some member of the family will notice a fullness in the neck, or more frequently, the teacher calls attention to the child's neck. On seeking medical advice the child does not have any complaints. The appetite is good and they are usually gaining in weight. The menstrual cycle is late in starting. This condition is usually seen between the ages of ten and fourteen, but more frequently around the age of twelve.

*Examination* Eyes are negative for exophthalmos. The neck reveals a soft symmetrical enlargement involving the entire gland. No masses can be palpated. There are no thrills

or bruits over the neck. The pulse rate is usually from eighty to ninety per minute. Blood pressure is normal. Physical examination is negative, with the exception of the findings in the neck. The basal metabolic determination will reveal a normal or diminished reading. This condition is an iodine deficiency disease, as has been pointed out by Marine. The hypertrophy is a physiological process which should respond to medication.

*Treatment* These cases will respond to iodine or thyroid therapy, but the mother should always be warned that it will take months, and in some instances years, for the enlargement to entirely disappear. Thyroid extract gr ½, T. I. D., seems to give better results than iodine medication. We always specify Burroughs, Wellcome preparation as it seems to be the most reliable. The dosage can be increased to gr 2, T. I. D., if necessary. It is important to stop the medicine one week a month to avoid a hyperthyroidism. After the condition is apparently cured the patient should report every three to six months for observation, and a short course of treatment. The prognosis depends on an early diagnosis. The neglected cases respond with much more difficulty and require larger doses of medicine.

*Adolescent Goiter With Hyperthyroidism*—This condition is encountered in from one to two per cent of adolescent goiters. The physical findings are not diagnostic of hyperthyroidism, although, the patient may have a slight thrill over the thyroid region, which suggests an over activity. The pulse is usually elevated above one hundred. There are no positive eye signs and there is no definite fibrillary tremor of the fingers. The basal metabolism determination is the only means of making a diagnosis. The rate is usually increased to a plus fifteen to

\* From the goiter clinic of Dr. Charles Gordon Heyd's service at New York Post Graduate Medical School and Hospital.

educate widely the profession with regard to the futility of the surgical measures so long in vogue

The physician of broad experience is coming to realize that the operative treatment of simple displacements has not withstood the crucial tests of time, that the method has not been generally helpful or even justified

A study of events disclose that the round ligament operation—a consuming epidemic procedure a few years ago—is now being employed only sporadically

The late beloved Watkins, shortly before he died, said "The round ligament operation seems to have ceased to be a subject of much general interest"

I am sure we are all familiar with the conservative trend in the treatment of simple displacements and this does not indicate that the trouble is less frequent, but that a mature surgical conscience has discovered therapy is rarely necessary

Indeed, if the conservative plan gradually evolved and adopted during the past few years could be regarded as a criterion of the future, it is obvious that uncomplicated cases will be treated, if treated at all, along ultra conservative lines. It is probable that simple malpositions will be regarded more from a physio-anatomic and not from a pathologic standpoint. Today the round ligament operation in uncomplicated cases, I rarely recommend or perform

The only type of displacement which one may legitimately place in the category of a surgical displacement is the large hyperplastic uterus, the large chronically inflamed adherent uterus or the pathologic prolapsed uterus. In these considerably more surgery than simply shortening the round ligaments or fixing the uterus forward is called for

The practice of major surgery for a minor condition is not good surgery and it is prudent to keep in mind that all forms of surgery exact a definite toll of human life.

The round ligament operation is no exception to this rule for it, too, has played its part of Shylock and taken infinitely more than its pound of flesh

After long study and several years of rather wide experience, I have reached the conclusion that uncomplicated uterine displacements rarely require treatment, either medical or surgical. Since the uncomplicated type is by far the most frequent, extensive use of the round ligament operation will gradually be abandoned

If one may regard a multiplicity of therapeutic measures as sound evidence that none are wholly satisfactory, then at least some of those designed for simple displacements may be included in that chapter. More than 100 different operative methods have been devised and next to the pernicious operation of dilatation

and curettement, I am familiar with none that have had less justification or done less good. Ten years ago the round ligament operation constituted more than ten per cent of the work of the gynecologist. I am persuaded that today it could be reduced to less than two per cent and all that is needed to see the consummation of this belief is a righteous surgical conscience. In simple cases it may be used occasionally as a matter of expediency in the course of other pelvic work, but rarely as a matter of principle or on primary organic grounds

As regards the therapy of anteversion, I have very little to say. To me it seems physically impossible to correct an ill developed anteverted uterus by either medical or surgical means

Personally, I believe a grossly maldeveloped anteverted uterus will remain maldeveloped and probably anteverted forever, irrespective of any type of treatment

So far as therapy is concerned, uteri of this form might legitimately be placed in the category of incurable conditions

If, however, the ill development is of moderate extent, some good may be accomplished by a restricted dietary regime, combined with the administration of organic drugs. Apart from these measures—and even they afford but slight encouragement to either the patient or the physician—there is little one can do

Surgery in the form of dilatation and curettement alone or combined with a uterine stem pessary or the various mutilating operations on the cervix itself, may occasionally provide some comfort but surgery, too, generally is disappointing, is not without features inimical to the integrity of the cervical mucosa and indeed not without danger even of a more serious character

The stand I have taken respecting the symptoms of uncomplicated displacement of the uterus, I realize fully, will not meet with universal approbation. It perhaps, on the contrary, will be greeted by condemnation, but I do believe I have expressed a conviction which is gradually becoming and is destined to become more and more universally recognized

I may be accused also of taking an ultra pessimistic point of view regarding the surgical therapy of simple displacements, but I feel justified in assuming a discouraging attitude because it is sustained first, by the decreasing frequency with which operations are being performed, second, by the almost universal condemnation of surgical means, and third, by the almost uniform failure in my hands of operative treatment affording symptomatic relief

Finally, may I say it is my last thought to appear before you gentlemen in the garb of a critic, for I am aware "Criticism often takes from the tree caterpillars and blossoms together" (Richter). I know too, that "Those readiest

## GRADUATE MEDICAL INSTRUCTION OR EDUCATION

The medical teaching of physicians is carried on by means of literature, lectures, and practical clinics. The value of the teaching varies from that of a medical society program which is beyond the comprehension of the members to that of a resident course requiring much concentrated study and practice.

There is much criticism over the application of the term "graduate education" to a series of didactic lectures, such as those usually given before county medical societies, and the proposal is made that they be called "graduate instruction."

The theory is that the word "instruction" is applied to the material that is offered by the instructors, while the word education is applied to that which the student assimilates.

The distinction between instruction and education is real and practical. The Medical Society of the State of New York offers courses of graduate instruction. It is hoped that they may result in the graduate education of the members of the County Societies that adopt the courses.

twenty-five. These patients usually have badly diseased tonsils, or an associated enlargement of the thymus, if an X-ray picture is taken of the chest. The treatment resolves itself into the elimination of any focus of infection, plus luminal gr  $\frac{1}{4}$ , T I D, with absolute rest. This means the child must be taken out of school, and, if possible, she should be sent to the country. Iodine and thyroid medication, needless to say, are contraindicated. If these cases do not subside within six months to one year, X-ray therapy seems indicated. The prognosis from the X-ray treatment seems more favorable if there is an associated thymus enlargement. Surgery is rarely indicated in this condition.

**Adenomatous Goiter**—This condition is rather rare in children, but it does occur in two or three per cent of cases. There is nothing significant in the history to differentiate it from adolescent goiter. It is usually associated with the beginning of the menstrual cycle. Examination reveals an asymmetrical appearance in the neck. The enlargement is usually confined to one of the lateral lobes, although, the isthmus may be enlarged. The mass is firmer than the surrounding thyroid tissue, which is not the findings of an adolescent goiter. Adenomatous goiter in children does take on a hyperthyroidism, which is denied by Helmholz.<sup>1</sup> Within the last year in this clinic, we have had two cases of hyperthyroidism in children from adenomatous goiter, one a male and one female. The boy was fourteen years of age and had a plus thirty metabolic rate. The girl was twelve years of age and had a plus twenty metabolic rate. **Treatment** Adenomatous goiter cannot be cured by internal medication, as one is dealing with an encapsulated tumor. There is always the danger of producing a hyperthyroidism in the adenomatous growth, from the indiscriminate use of iodine. In one case cited above, the boy fourteen years of age, presumably, had the hyperthyroidism induced by taking some form of thyroid medication, which he had taken for about four weeks before coming to the clinic. The only permanent cure in this condition is a partial lobectomy. If the parents do not wish to submit the children to an operation, it is best to keep them under observation, without medication.

**Exophthalmic Goiter or Graves Disease**—This is the most frequent type of hyperthyroidism encountered in children. The same cardinal signs

and symptoms are found as in an adult, namely, tachycardia, tremor, exophthalmos and goiter. Of the secondary signs and symptoms, diarrhea is quite a serious complaint. It is more frequently seen in children than in adults, and it is occasionally mistaken for a primary gastro-enteritis. Loss of weight and a general state of irritability are usually seen. One should bear in mind that children do have Graves' disease and age is not a contraindication. Helmholz in a recent report from the Mayo clinic gave the youngest child as three years of age. White<sup>2</sup> has reported a case of congenital exophthalmic goiter. **Treatment** Children seem to respond less favorably to conservative treatment than adults. Partial thyroidectomy seems preferable to other types of treatment during childhood. Helmholz states that preliminary ligation was performed in only four of twenty-one patients who were operated on after the introduction of the compound solution of iodine. Dinsmore<sup>3</sup> states the treatment of hyperthyroidism is the same whether the patients are children or adults, excepting that it should be borne in mind always that special care must be exercised in handling these children. They are very susceptible to every form of stimuli and may be very ill after operation. In nearly every instance it is necessary to ligate the superior thyroid artery, first on one side and a few days later on the other side, three months before thyroidectomy is performed. From the above statements it would seem that the individual case has to be taken into consideration, and whether a preliminary ligation is performed before a partial thyroidectomy depends entirely on the reaction to the preliminary treatment.

**Conclusions** 1. Adolescent goiter is amenable to thyroid medication. 2. One should be careful to make a differential diagnosis between adenomatous goiter and adolescent goiter, as thyroid medication is contraindicated in the former. 3. Graves' disease occurs more frequently in children than has been generally supposed.

many convictions. The reasons for the inactivity of the Legal Department of the city were not discussed, but they are analogous to those for inactivity against gold brick schemes. So long as alluring promises of rapid wealth or health are made, just so long will a considerable number of people put their property or their bodies into the hands of the schemers, and will not begin prosecution for failure to receive the returns that were expected.

Dr Rypins introduced a new line of thought when he said that chiropractic was a variety of faith cure. He told of an official inspection of the Palmer School of Chiropractic, the original fountain head of chiropractic, and how the instructors instilled the idea of implicit faith in the system into the minds of the students. The deflections of the needle of an electric thermopile called a neurocalometer, applied to the back were interpreted as indications of the flow of nerve force from the spinal cord along the nerves. And when Dr Rypins showed that the same deflections occurred when the instrument was applied to the hand, the instructors and students would not listen to him, but adhered with blind faith to their own interpretation of the deflections.

The validity of Dr Rypins' testimony was confirmed by the experience of the representative of this Journal immediately after the close of the hearing when physicians and chiropractors mingled in friendly conversation. The Journal representative asked two gentlemanly chiropractors "Do you really and truly believe that you can tell what organ is diseased simply by viewing and feeling the spinal column?" and they earnestly replied, "We do," and wanted to prove it then and there. "How then does it happen," the medical reporter asked, "that the theory of nerve control and the art of chiropractic is taken up by not a single research laboratory of a university, nor by a scientific foundation like that of Rockefeller or Carnegie, nor has the financial endowment for its investigation and promotion been provided by a single rich man or chiropractor?" And the quick reply was, "All that is coming in the near future. Newly discovered truth has always been opposed and its proponents persecuted. Even Harvey was imprisoned for announcing the discovery of the circulation of the blood."

"Your history is as faulty as your science," was the reply of the medical reporter as he hurried away to prepare his copy.

### MOVING PICTURES IN MEDICAL TEACHING

The value of moving pictures in medical teaching has been widely debated. It is not a short cut to knowledge, as enthusiasts claimed twenty years ago when movies first came into use. There is no such thing as a short cut to information, for knowledge can be acquired only by patient effort. A picture on a screen is evanescent, and it becomes knowledge only when it is graven deep on the firm tablets of memory.

The preeminent value of the moving picture is that it opens up another avenue of approach to the mind. A description, either written or spoken, is a slow and laborious method which may be likened to successive peeps through a

telescope with a narrow angle of vision. The moving picture is a window overlooking the whole field of view on which an action takes place. It introduces the visible conception of a sense of thickness, which is difficult to impart by verbal descriptions and still pictures.

The movies also have other advantages which are well expressed in an article by Dr J F Montague, printed on page 176 of this issue. The author has spent an immense amount of time and effort in securing a series on the subject of proctology. It may be that if other picture-makers would put forth equal effort, movies would occupy a more important place in medical teaching.

---

### THE THREAT OF INFLUENZA

The question of a recurrence of influenza this Winter and Spring is under serious consideration by health officials. The United States Public Health Service publishes the figures of the prevalence of the disease in centers of population throughout the world. These reports indicate that the aggregate of cases is about that of other years during this season of the year, and that the rate of incidence is diminishing at about the same rate as it usually does.

The late Dr Otto Eichel, Chief of the Division of Vital Statistics of the New York State Depart-

ment of Health, had made extensive studies of influenza in the past, and with great patience and perseverance had plotted mathematical curves of prevalence during several epidemics. He had also plotted curves for the incidence of cases during epidemics of other diseases, especially poliomyelitis. He formulated a theory that the curve of onset of an epidemic could be expressed by the same mathematical formula as that of its decline; and that the complete curve from the onset through its peak and its decline formed a parabola, or some other well-known mathematical

## A NOVEL PROGRAM OF A MEDICAL SOCIETY MEETING

How to conduct an effective scientific program of a meeting of a medical society was beautifully demonstrated on January 29 by the Associated Physicians of Long Island when it carried out a varied program of 18 papers in 90 minutes

To carry out this program required preparation. The speakers were members of the staff of the Methodist Episcopal Hospital, Brooklyn, where the session was held. Each speaker was required to write his paper within a limit of 600 words. The Chairman appointed a timekeeper who started an alarm clock set for five minutes, and it did not go off once, for every speaker completed his remarks ahead of time.

The program carried this announcement:

"The whole story of creation is told in the Bible in 600 words. Anyone who has a real message to give can do it in five minutes. The presiding officer will be asked to use his gavel if any of the speakers on this program exceeds his time."

The effect of the program was most happy. The one hundred or more physicians who were present gained a wealth of new ideas, and every moment of the time was interesting.

What kind of program was carried out by the meeting? Just such a program as is prepared for an average county medical society. Here it is just as it was printed:

"Subacute and Chronic Sinusitis in Children," Kenneth E. Millan

Frequency of its occurrence and variety of conditions proceeding from it.

"Gangrene of the Uterus Due to Torsion," Henry T. Hagstrom

Operation. Case report. Natural color photographic lantern slides.

"Blood Transfusion," Seymour G. Clark.

Indications. Contraindications. Discussion of abuse of the method with illustrative reports and fatalities.

"The Relation Between the Preparation and the Morbidity in Obstetrics," Harry W. Mayes

Statistics showing effect on morbidity of shaving and cleansing of the external genitalia before using the mercurochrome preparation.

"The Use of the Bronchoscope," Einar A. Sunde.

Indications, contraindications and results in abscess of the lung.

"Exhibition of Interesting Cases," Eugene S. Dalton.  
From the medical ward.

"Bone Cysts in Children," Harold K. Bell.  
Report of two cases. Lantern slides.

"Manikin Demonstration. The delivery of a face," G. Hamilton Davis

Presentation with the chin posterior.

"Hare Lip and Cleft Palate," Roger Durham.  
When and how to operate. Lantern slide demonstration.

"Umbilical Hernia in the New Born," Ralph M. Beach.  
Operation. Case report. Lantern slides.

"Phosphatic Cast of the Bladder," Howard T. Langworthy

Case report. Discussion of the difficulties in the treatment of alkaline urine. Measures that have been tried. Results.

"Appendicitis Complicating Pregnancy, Labor and the Puerperium," Robert A. Wilson.

Tabloid case reports. Frequency and prognosis and, especially, the treatment.

"Electro-cardiograms," Alexis T. Mays

Lantern slide demonstration illustrating their definite value in diagnosis, prognosis and treatment.

"The Use of Radium at the M. E. Hospital," John C. Graham

Five years' experience. Indications. Contraindications. Results.

"The Kahn Precipitation Test for Syphilis," Esmond B. Smith

Experiences in 800 cases at the M. E. Hospital. Conclusions.

"The Use of Numequin in Pneumonia," Frank B. Cross.  
Analysis of results in 200 cases.

"Caudal Anæsthesia for Rectal Operations," Henry F. Graham

Difficulties. Unpleasant reactions and how to avoid them. Brief statistical review.

"Early X-ray Diagnosis of Infections of the Lung," William H. Wallace.

Lantern slides.

The quality most needed in a medical program is conciseness, in contrast with the prolixity which is often in evidence. To make and carry out a program such as has been described requires only a single essential—that of accurate preparation. Every county medical society has the talent and the clinical cases readily available as the basis for an hour's program consisting of twelve five-minute papers.

## THE CHIROPRACTIC HEARINGS

The Joint Committee of the Senate and Assembly on Chiropractic has completed its investigations after having listened to witnesses during six sessions of about two hours each. Four of the sessions were given to the chiropractors, and the reports of two of those sessions were printed in the January 15 issue of this Journal.

The last two sessions were given to those opposed to the legal recognition of chiropractic, and a report of the proceedings is printed on page 201 of this Journal.

When the opponents have raised objections based on the harm that the chiropractors might do, the question in rebuttal has often been "Have you seen any harm resulting from the chiropractic treatment?" The insinuation and implication is that chiropractic does not harm the patient even if it does no good. The testimony of Dr. Louis I. Harris, Commissioner of Health of New York City, showed that while numerous complaints against chiropractors came to the Department of Health, the District Attorney was not securing

## MEDICAL PROGRESS

**The Warfare Against Rabies**—H Lubinski of the Hygienic Institute of the University of Breslau begins a long article on this subject with the statement that following the war there has been a global increase of rabies (the author restricts the word rabies to the disease as it affects dogs and employs the term *lyssa* for human rabies) There has been a corresponding increase in bites of mankind by rabid dogs and in the number of cases of human rabies The author discusses the immune virus, its preparation, conservation, testing for virulence on animals, dose, etc, different health offices using some one method by preference with a general absence of standardization In some localities the mortality among the vaccinated after exposure is as low as a fourth of one per cent, while the high figures are between 1 and 2 per cent These figures must be compared with the 10 to 20 per cent mortality among the unvaccinated The second great problem of prevention, which includes the measures in use in communicable disease in general, involves the immunization of all dogs and hence is a serious problem which can be carried out ideally only for whole countries and not merely for special districts in which the disease is prevalent This has been tried out on a large scale only in Japan and America where inoculation of several hundred thousand dogs caused a notable decline in rabies The measure is not a popular one, for in the minds of the people a bite by a freshly immunized dog is thought of as a possible source of disease In the few cases in which dogs have shown rabies after immunization, bites by stray rabid dogs were probably at fault—*Klumsche Wochenschrift*, November 19, 1926

**The Effect of Emotion on Certain Cases of Asthma**—Lloyd H Ziegler and David C Elliott, writing in the *American Journal of the Medical Sciences*, December, 1926, clxxii, 657, call attention to the frequency of neurotic factors in certain cases of bronchial asthma Graham Brown has reported a case of asthma which developed after long fear, and offered in explanation the theory that fear exhausted the adrenals and left the patient with a marked vagotonia, which vague syndrome seems to be present in many asthmatics In order to test the effects of emotion, the authors carried out experiments on two groups of asthmatic patients, one of persons with definite protein sensitization and the other consisting of patients who at one time or another exhibited

some definite neurosis or psychosis In the latter group, the expiratory phase of respiration, which is usually unduly prolonged in asthma, became definitely lengthened in the psychopathic group under emotional strain, and was accompanied by other manifestations, such as purposeless movements and fine tremor, during the emotional stimulation The pulse rate was rapid during the whole experimental period of emotional stimulation, though no changes in the characteristics of the electrocardiogram were noted The respiratory rate was not increased, but its amplitude and regularity were markedly altered by the emotional stimulation The patients who were definitely sensitive to protein showed no response to emotional stimulation In the absence of protein sensitization, or of a history of the same, a careful study of the relation between emotions and asthmatic attacks is indicated, and should help to explain the disease in a limited number of patients

**Presenility Resulting from Endocrine Disturbances**—F M Groedel and G Hubert begin their article with a quotation from Lorand to the effect that in senility and especially precocious senility, there is an increase of connective tissue in all parts of the body and especially in the endocrine glands He even makes this phenomenon the principal cause of precocious senility Therapeutically therefore he makes use of hormones, along with iodine as the leading constituent of the thyroid The authors in their personal experience of these cases state that as a rule these subjects—called technically “sclerotics”—experience a rather abrupt failure of their forces after a record of uniform health The variability among the patients is associated in some way with differences in the participation of the endocrines and other organs In some cases there is an increase rather than diminution in some endocrine functions, as the thyroid or gonads Aside from the endocrines the participation of other structures may dominate the picture as in coronary sclerosis or sclerotic kidneys, but these cases are not of interest in the present connection as the authors are concerned chiefly with sclerosis of the endocrines

To cite a case in point, a healthy woman of 78 suddenly began to lose strength and weight without apparent cause, carcinoma being excluded Interferometry, as recommended by Hirsch, which has to do with a modification of the Abderhalden reaction, showed that three of

figure, which could be expressed by a simple algebraic formula according to the principles of analytic geometry

Dr Eichel's theory is confirmed by common experience with epidemics in which the incidence of cases has been known with accuracy. The epidemic of 1918, for example, was thoroughly studied in a military population of 40,000 soldiers during the world-wide epidemic which occurred in the Fall of 1918. The first recognized cases in New York State were discovered in Camp Upton early in September, and the disease spread in circles from the original cases to those soldiers which were in contact with them. Quarantines were established by companies, which is the usual army procedure, but they were carried out with extremely unequal degrees of efficiency. While cases occurred in all companies, yet in some the incidence was as great as fifty-five per cent of the members, and in others only three per cent.

Moreover, when the epidemic began to decline, the disease broke out in new centers with diminishing frequency, as the companies relaxed the vigilance of their quarantines, and the curve of the decline was the same as that of the onset. This fact became evident when accurate figures were compiled at the close of the epidemic, and were confirmed by the experience in a few villages up-State in which the disease originated in a known case and ran its course without the introduction of new sources of infection.

The method suggested by Dr Eichel affords the means of prognosis regarding the probability of an extensive outbreak in New York State this year. While the reports of cases are incomplete, yet they are probably more accurate than ever before, because physicians and health authorities

are more efficient in making the reports. The opinions of the leaders of the United States Public Health Service and the Departments of Health of New York State and City as quoted in the daily press, are that the prevalence of influenza this year will be about the same as that during the past two or three years.

Dr Eichel's theory also applies to the incidence of influenza during cycles of years. Extensive epidemics of great virulence occur about once in thirty-three years. The general trend of the curve has been downward since the year 1918, and may be expected to continue downward during the next decade. But within that time it may be anticipated that persistent research will reveal the exact nature of the disease, and efficient measures for its prevention.

For the present, isolation and quarantine appear to be the principal means of prevention, and they are almost total failures because they must be applied to every individual case during the first two or three days of onset. This would mean that every person who has an acute "cold" should voluntarily stay at home and away from other persons. But that is something which neither individuals, nor employers, nor society will permit. The reporting and isolation of fully developed pneumonias are difficult to secure. Much less then are physicians and the people generally prepared to isolate cases of "colds" and sore throats.

Practical measures for controlling influenza will probably have to await the discovery of the means for bacterial detection and identification which are as accurate as those for the detection of the bacteria of diphtheria and typhoid fever.

## LOOKING BACKWARD

### THIS JOURNAL TWENTY-FIVE YEARS AGO

Twenty-five years ago this Journal established a standard of friendliness to its advertisers which has actuated the Medical Society of the State of New York for a quarter of a century. The Journal of February, 1902, contains the following editorial which is as apropos now as the day it was written:

*"Our Advertisers.* The Publication Committee intends to lay special stress on one of the unwritten laws which have guided it in admitting advertisers to our columns. The Association desires to introduce to its members only those houses whose reputation for commercial integrity is such as to guarantee that their products will be what they are represented to be. If one of our members, overpersuaded by clever advertising, buys what he does not need, it is his own fault, but if, through our columns, he buys something

which is not what it was represented to be, the blame may, in part, be imputed to the Committee.

"We shall admit to our columns no firm which we cannot recommend to the patronage of our members as honest and reliable, and we shall be under obligations for any evidence to the contrary which may be presented.

"In return, our members have certain obligations toward the advertisers in their journal. We enter into no contract to guarantee them sales, but we do contract to give them an audience and it is the duty of the Association members to personally make good the promise made in their name.

"Not only actual purchases, but every letter of inquiry mentioning THE NEW YORK STATE JOURNAL will be accepted as evidence of the value of our advertising space."

ministration of iodine, and physicians should understand the dangers attending its incorrect use

**Iodized Oil in the Treatment of Bronchiectasis**—A supraglottic method of injecting iodized oil, which is applicable for both diagnostic and therapeutic purposes in bronchiectasis is described by Bruce Whyte (*Canadian Medical Association Journal*, December, 1926, xvi, 12). With the patient seated, the soft palate and posterior portion of the tongue are anesthetized by swabbing with a 5 per cent solution of butyn or a 10 per cent solution of cocaine, then with a small syringe 1 to 3 c.c. of a 2 per cent. solution of butyn is injected into the larynx, with the aid of the headlight of a laryngeal mirror. After waiting 5 to 10 minutes, the tip of a 20 c.c. laryngeal syringe, filled with iodized oil, is placed over the patient's open glottis and 15 c.c. of oil injected in 30 seconds. After completing the injection the patient continues to breathe steadily and to hold his tongue for half a minute. Fluoroscopic and roentgenologic examinations can then be made. The deposition of the oil can be controlled by the position of the patient. For example, for filling a bronchus on the right side, the patient's trunk should be inclined to the right. The intervals between injections are governed by the quantity of oil required. In the writer's practice 5 to 20 c.c. of the oil have been injected at intervals of 5 to 14 days. The duration of the treatment depends upon the tenacity of the symptoms. Thirteen patients receiving these injections showed decided improvement. With this treatment symptomatic improvement has also been reported by Armand-Dehille and Nicaud and Dollfuss.

**Treatment of Serous Pleurisy by Auto-injections**—J. de Hartgohe of Amsterdam began to treat serous pleurisy by autoserotherapy in 1920 and relates six case histories which occurred during the interim of six years. He does not mention the experience of others in this field beyond crediting Gilbert with originating the method in 1894, but discusses the nature of the favorable results which must be ascribed either to the action of an antigen in the serum or to protein stimulation—possibly to both factors acting in concert. His conclusions are in part as follows. In acute primary serous pleurisy autoserotherapy furnishes a resource for cutting short the duration of the disease. A diagnostic puncture should be made before the injection and one should not wait long before injecting after the diagnosis is made. Study of the case histories appears to show that the injections are not practised until after other ordinary measures have failed to give relief and the patients who were injected were, or made

the impression of being, very sick. In other words there was evidently nothing experimental about this plan of treatment. The cases cited appeared to be given to illustrate the special types of the disease in which the treatment might or might not prove of value. One old man died under the treatment without experiencing any benefit, while another patient not only failed to benefit but developed hemoptysis. On the other hand in several cases the benefit was not only prompt but decisive, the injections having been followed by defervescence, diuresis, relief of pain, etc. The puncture fluid was merely injected under the skin of the upper arm. When benefit followed the first injection no second one was practised, but in the cases with tardy response the injections were repeated at daily intervals.—*Nederlandsch Tijdschrift voor Geneeskunde*, December 11, 1926.

**Etiology of Mycosis Fungoides**—S. R. Brünauer gives a brief outline of the history of our knowledge of this affection with especial reference to the obscurity of its origin. One source of difficulty lies in the absence of type of this disease which caused Zumbusch to distinguish at least three different forms (of which one shades into sarcoma), suggesting corresponding differences in etiology. The author, having under observation a case of the generalized type, succeeded in communicating it to guinea pigs. The inoculation material was taken from the cadaver of the deceased patient and comprised material from the skin and viscera as well. The site of inoculation was the subcutaneous tissue of the abdomen. No lesions *in situ* are mentioned, but after nine weeks' incubation nodules developed in the liver and spleen which were identical histologically with those in the human subject. The author mentions the continuous failure of observers for many years past to isolate or cultivate any form of organism from the lesions of the disease, save certain finds due to secondary infection. No successful animal inoculations are mentioned except some finds by Ceelen in which guinea pigs were also used but which histologically were not identical with mycosis. The finds of the author if accepted will place the disease back among the infectious granulomata. It is doubtful however if any light has been thrown on the cause of the disease in man. Several efforts to inoculate macacus monkeys were in vain, and there is no suggestion of transmissibility from man to man. Even the possibility of general infection from a local focus is in doubt. French observers used to speak of a "mycosis chancre" but since the employment of roentgen diagnosis this notion has not been upheld.—*Deutsche medizinische Wochenschrift*, November 26, 1926.

the ductless glands—ovary, thyroid and hypophysis — were undergoing retrogressive changes, this indicating in almost every case a lowering of the function. In two middle-aged men whose cases are recorded, arteriosclerosis was prominent and the interferometric blood test showed an atrophic state of the testicle. Many other cases are reported in which the presence of such lesions as arteriosclerosis in the aorta and various other localities, sclerotic liver and kidneys, suggests a sclerosis of the endocrine glands. However, in certain of these cases of clinical sclerosis the test showed that some or all of the endocrines were not abnormal and in this type of case the use of hormones would not be indicated. The authors sum up as follows. In progressive arteriosclerosis we often find a strong disintegration of some of the endocrine glands indicating a lowered function of the same. Only one gland or several may be implicated. The authors have not carried out the gland treatment long enough to determine its utility in these deficiency cases but are quite hopeful as to the result.—*Deutsche medizinische Wochenschrift*, November 19, 1926

**Tropical Typhus and Brill's Disease**—William Fletcher and J. E. Lesslar, writing in the *Journal of Tropical Medicine and Hygiene*, November 15, 1926, xxix, 22, point out that the epidemic typhus fever of Eastern Europe has its feebler image in tropical typhus. Epidemic typhus is essentially a disease of cold and temperate climates, when it breaks out in subtropical countries it flares up in winter and dies down in the spring, while tropical typhus appears in spring and dies down in winter. The symptoms of epidemic typhus and tropical typhus are the same, both diseases run the same course, and in both the Weil-Felix reaction is positive, but the two diseases are totally different from the standpoint of the sanitarian and the public.

Tropical typhus does not spread from man to man, does not give rise to epidemics, is not carried by lice, special precautions to avoid infection are unnecessary, and the mortality rate is low. In tropical typhus, as shown by Von Loghem, two groups of *B. proteus* are concerned. (1) The *indologenes*, which produces indol in peptone water, and (2) the *non-indologenes* group which does not react thus. The authors have employed in the Weil-Felix reaction, a nonindologenic strain of *B. proteus* x 19 (Kingsbury) and a number of indologenic strains, and in this way have demonstrated the two groups of tropical typhus. One group, which they call K, agglutinates an anindologenic strain (Kingsbury) but does not agglutinate the indologenic strains, such as Warsaw and No. 67 from the National Collection of

**Type Cultures** The second group, W, agglutinates the indologenic strains, but does not agglutinate the nonindologenic strains. These two groups seem to be equally common in the Malay States, they differ but little in their course and symptoms. In neither group is there evidence of transmission by lice, but there is reason to suspect that the disease is conveyed by an ectoparasite of the rat or the mouse, as the disease has a tendency to attack cattle keepers and agricultural workers. The authors point out the similarity of tropical typhus and Brill's disease, which, as described by Brill, resembles typhus fever more than does any other disease, but, unlike typhus, is not communicable, not a grave and fatal malady, and epidemics do not arise, though it is constantly present in the community. These mild forms of typhus-like fever are widespread, having been reported from every quarter of the globe. It is important in using the Weil-Felix reaction to make two cultures of *B. proteus* x 19, one indologenic and the other nonindologenic, in every case.

**The Incorrect Use of Iodine in the Treatment of Goiter**—Donald Guthrie, writing in the *Therapeutic Gazette*, December 15, 1926, lxi, 12, asserts that the wholesale administration of iodine in water supplies, table salt, candied tablets, tinctures, and salves has unquestionably injured hundreds of persons with goiter. Physicians having goiter patients coming to them for consultation are amazed at the prevalence of this incorrect use of iodine, not only self administered, but unfortunately frequently incorrectly prescribed by physicians. The scope of iodine therapy in the treatment of goiter is thus summarized. Iodine in very small amounts will prevent the development of the simple colloid goiter of adolescence, and will also cure a certain number of the goiters of adolescence. These patients should remain under observation while the treatment is given. It is unsafe to give iodine in any form to the patient with colloid goiter after the age of 25, for the glands in these patients contain small adenomata which may be activated by its use. Iodine should never be given in any form or any amount to the patient having rounded goiter of long standing, since these quiescent adenomatous goiters will become toxic. Goiters of this type can be removed surgically with great safety, there is no medical treatment that is safe. Iodine should not be given to any adenomatous goiter patient who is already toxic. The iodine treatment for exophthalmic goiter is not a curative one, it is merely a mode of treatment whereby the exophthalmic goiter patient is prepared for operation, and is best given in a hospital. The public should be warned of the great danger of the self-ad-

# LEGAL

By LLOYD PAUL STRYKER, Esq  
Counsel, Medical Society of the State of New York.

## ARBITRATION ONE OF THE MOST IMPORTANT POWERS VESTED IN THE NEW COMMITTEE ON GRIEVANCES

With the huge mass of litigation literally overpowering our courts of justice, both federal and state, businessmen have long since adopted the principles of arbitration in the settlement of their differences. By this means technicalities to a large extent are done away with, expense is avoided and, above all, a prompt disposition of the matter can be had. The state courts in the metropolitan district are from one and one-half to three years behind in their calendars, while the federal courts, in civil cases, are now trying actions which were commenced four and five years ago.

Where each of the parties to a controversy believes in the respective merits of his side, they are not afraid to submit the determination of their case to a prompt, fair and impartial tribunal, each knowing well that if justice and right are on his side, his contention will prevail.

Of the many enlightened and forward-looking provisions of the new Medical Practice Act, none is more important, more modern or more harmonious with present-day conceptions of justice than the arbitration clause contained in subdivision 6 of Section 174-b, which reads:

"Any controversy between two or more physicians, or between a physician or physicians and another person, which said parties to such controversy agree to submit to arbitration, may be submitted in writing to said committee on grievances, which may in its discretion act as arbitrator in said controversy, and the decision of said committee upon such arbitration shall be final, and where the same orders the payment of a sum of money, the same may be docketed as a judgment of a court of record and enforced as such judgment, provided the terms of the arbitration include such provision."

In considering the scope and extent of the powers vested in the Committee on Grievances by virtue of this section, the following ideas should be clearly noted:

First The Grievance Committee has no power to arbitrate or decide any question unless both parties to the controversy consent to submit their differences to the Committee for its decision. The Committee has power to decide those controversies only "which said parties to such controversy agree to submit to arbitration."

Second The controversy thus made arbitrable is one either "between two or more physi-

cians or between a physician or physicians and another person." Thus doctors may, by means of this arrangement, receive a prompt and fair decision of such differences as may arise between them. In the same manner a controversy between a patient or any person and a physician may likewise be submitted to this tribunal for its decision. Thus any patient feeling himself aggrieved by the professional treatment accorded to him by his physician may, if both he and the physician agree, submit their controversy to the Committee on Grievances for its determination. Any controversy, therefore, which heretofore was necessarily determined through the public and harrassing means of a malpractice action in the courts may now be decided promptly, privately and economically by the Committee, provided both parties to the controversy "submit to arbitration."

Third The nature of the judgment which may be rendered in arbitration is clearly defined. In the first place, the law provides that the "decision of said committee upon such arbitration shall be final." This does away with the "law's delay" so often attendant upon a long succession of appeals. Under this provision, when the Committee decides, it decides once and for all time. Its decision is a final one and the controversy ends there once and forever. Where the Committee awards a sum of money, its award "may be docketed as a judgment of a court of record and enforced as such judgment." But the Committee is without power to make such judgment unless "the terms of the arbitration include such provision", that is to say, the award of the Committee can be docketed as a judgment of a court of record only where the parties to the controversy in advance so agree.

Thus it is apparent that the whole arbitration plan embodied in the statute rests upon the voluntary consent of the parties to the controversy. The parties may invoke this machinery or they may not. It cannot be invoked without their consent.

As time goes by it is our prediction that the salutary and forward-looking powers of arbitration will be frequently invoked both by the laity and the profession. From time to time the writer has had his attention called to extremely acrimonious disputes between doctors arising out of their professional relations and from differences as to what the proper observance of ethi-

**The Control of Pain Through the Nasal Ganglion**—For the relief of all syndromes related to the nasal ganglion, both the neuralgias and the sympathetic reflex syndromes, John Edward Loftus (*Therapeutic Gazette*, December 15, 1926, xlii, 12) describes a method of injecting the nasal ganglion. The simple painting of the region of the sphenopalatine foramen with cocaine (2 to 90 per cent), formaldehyde, or silver nitrate, is often curative but difficult because of the irregularities of the septum or the configuration of the turbinates. The injection is made by the use of a simple straight needle fastened in a heavy crossbar, which enables one to secure it in a strong grasp and put great pressure upon it. For the lateral wall a curved needle of the same style is often more convenient. The ganglion is cocaineized by an applicator carrying one drop of saturated (90 per cent) watery solution of cocaine hydrochloride placed under the tip of the middle turbinate, then moved to lie over the sphenopalatine foramen just behind the posterior tip of the middle turbinate, where it is allowed to remain for five minutes. Following this, 0.5 cc of a 5 per cent phenol solution in 95 per cent alcohol is injected. The injection is followed by a slight sense of pain, different from the neuralgic pain, which lasts from 2 hours to 3 days. In old and severe cases the injection may have to be repeated as often as ten times. This treatment has been found useful in all cases of earache from eustachian tube and middle-ear inflammation, cases of spasms of the entire face accompanied by spasms of the throat, larynx, esophagus, and diaphragm. It has been effective in a case of lower half headache, and in the control of intercostal pain, gastric pain, nausea, vomiting and diarrhea of reflex origin, nodular headache, syphilitic headache. Certain cases of hay-fever which do not respond to specific protein treatment are relieved by cocaineizing the nasal ganglion. In neuralgic syndromes, starting as an acute coryza, in which pain later develops around the root of the nose, in and about the eye, upper jaw, teeth, and sometimes in the lower jaw, extending backward to the temple, zygoma, and mastoid, often to the shoulder, axilla, arm, and hand, these injections afford relief.

**Nascent Iodine in Otorrhea**—In the routine treatment of middle-ear suppuration nascent iodine has given F. Pierce Sturm better results in both acute and chronic cases than any other method of equal simplicity at present available. Even in acute mastoiditis, where operation has

been refused, it has cured apparently desperate cases. The adult patient takes internally 10 grains of potassium iodide, well diluted, every four hours. Every two hours, or even more frequently, the external meatus is filled with hydrogen peroxide, which is retained for ten minutes. The resulting reaction between the absorbed salt and the applied drops liberates nascent iodine within the tissues of the infected middle ear cleft. With variations in the dosage of the active salt, according to age and idiosyncrasy, the treatment is useful in every case of suppurative otitis media.—*British Medical Journal*, December 11, 1926, ii, 3440.

**Diphtheria Problems**—Professor R. Degkwitz, the pediatricist, writing in the *Klinische Wochenschrift*, of December 3, 1926, sums up our present day knowledge in the light of the ancient and recent history of the disease. It is accepted as proven that if a subject have antitoxin in his blood he is immune, if not, he is susceptible. Unless the person has recently recovered or unless he has been immunized artificially, that is in the naturally immune, how is the antitoxin formed? We can only surmise that he has been immunized by a mild attack or through being a carrier. Originally a disease of this sort is regarded as a pandemic and later it becomes endemic. In time all of the adults become immunized, leaving the young children as the natural victims of these diseases, whence the term "contagious diseases of childhood" for measles, whooping cough, mumps, smallpox, and so on. But this does not mean that children are essentially more susceptible to contagion. It is evident that the immunity acquired by the adult is not inheritable. In the middle of the XIX century (1847) diphtheria was practically unknown in Germany. French accounts of it were looked upon with suspicion. When in 1849 it began to appear in Germany it attacked mostly children. Yet the study of history shows that the disease had prevailed over a century before. There is no reason to believe that the bacillus had disappeared, but doubtless it had lost its virulence as a pathogenic agent while still able to immunize the community. This of course invokes the theory of mutation. It is evident that the virulent and non-virulent forms may exist at times side by side, the new generation being infected by virulent carriers. The natural immunes have evidently been immunized somehow by non-virulent carriers, these of course give a negative reaction to the Schick test.

# NEWS NOTES

## DINNER TO DR WENDELL C PHILLIPS

The Medical Society of the State of New York gave a dinner in honor of Dr Wendell Christopher Phillips on the evening of Thursday, January 27th, at the Hotel Waldorf-Astoria, New York City. Over four hundred guests were present, including the officers and members of committees of the State Society, and members from the far ends of the State. The arrangements were in the immediate charge of a committee consisting of Dr N R Van Etten, Chairman, Dr D S Dougherty, Dr J E Jennings, Dr W H Ross, and Dr O S Wightman.

The occasion was in honor of the presidency of the American Medical Association which has been filled by Dr Phillips since May, 1926. The dinner was in a sense his home-coming to his own organization and intimate friends.

The career of Dr Phillips was happily reviewed by Dr George M Fisher, toastmaster, and President of the Medical Society of the State of New York. "Dr Phillips," he said, "has risen from the ranks to the highest position of honor and responsibility among the physicians of the United States. Graduating from the New York University Medical College in 1882, he at once became active in the New York County Medical Society and served as its president in 1904, and as president of the Medical Society of the State of New York in 1911. He was elected a trustee of the American Medical Association in 1918, and became its president in 1926.

"Dr Phillips was also prominent in the societies of his chosen specialty, and became president of the New York Otological Society and the American Laryngological, Rhinological & Otological Society.

"A striking point in his career was the fact that he always became a leader in whatever society he worked, and soon attained to the presidency of nearly every one. It therefore is true that the life of Dr Wendell C Phillips is a record of medical progress during the last four decades.

"But we are not here merely to recognize the honors to which Dr Phillips has attained. A man is not remembered for what he has amassed for himself, but for what he has given to others. Dr Phillips has been untiring in urging his fellow physicians to adapt themselves to the methods of practice that are demanded by the recent progress in preventive medicine. His inaugural address as President of

the American Medical Association was a vision of what the family physician will be in the near future when medical knowledge that is already at hand is applied in every-day practice. In that address he emphasized the expression, 'Every Physician a Health Teacher,' and that ideal will soon be attained if one may judge him by his success in his past prophecies.

"The spirit of service which has actuated Dr Phillips has led him into medical activities outside the medical profession. He was the organizer of the New York State Society of the Hard of Hearing, and the first president of the American Federation of Organizations of the Hard of Hearing,—societies which have been of incalculable benefit to the deaf."

Dr Samuel Lambert, President of the New York Academy of Medicine, brought the cordial greeting of the members of the Academy, which is composed of men of the highest standing in medicine in New York City and its vicinity.

Dr Harlow Brooks, Past President of the American Society of Physicians, brought the greetings of that organization, and said:

"This is a delightful family party. I can't look on it as anything else. Dr Phillips always did have a large family around him, his or others', it made little difference, and we all feel we have gathered around him for so many years as our leader, as though he owns us.

"Those of you who read his inaugural address of only a few weeks ago, I think, read one of the most notable addresses which has ever been given by a medical speaker in this country. There was no equivocation about what he meant. He announced a policy which it seems to me, and I think to all physicians, does seem to be one of the outstanding, progressive policies of the physician. It was not always popular, but it has to be popular now to break down the Brahmanistic barrier which lies between the profession and the people whom we serve. I think that Dr Phillips has made it the policy of the profession over the entire country willy-nilly (and most of us think it is willy) to break down this unnecessary fetish which has stood between us and our patients, and we now can approach the patient in a much more direct way. We can approach the press in a much more direct way. We can approach all medical organizations and all social organizations and bring them together, to unite in a greater work.

"It is quite beside the point to say anything complimentary about Dr Phillips. We know him. He is one of us. He has been our leader.

cal conduct in a given case required. At least one such controversy is recalled which resulted in a very bitter libel suit in court brought by one physician against another. Such an action necessarily results in publicity and no matter who wins the case, both parties to the action, to an appreciable degree, are the losers as a result of the public airing of their dispute.

As the Grievance Committee becomes better known and understood and earns, as in our opinion it undoubtedly will earn, the respect and confidence of the laity as well as of the profession, an honest patient feeling that he has been aggrieved by reason of the treatment accorded him by his physician, will be willing to submit his complaint to arbitration. Where such a state of mind exists on the part of the patient, we are confident that it will be reciprocated by the physician.

What tribunal could be more competent to decide whether or not, in a given situation, a doctor has followed proper and approved practice and has complied with those duties which rest upon him, than a committee of doctors whose whole lives have been devoted to a study of the healing art? Where doctors and patients agree to arbitrate their differences, all of the unpleasant features of a malpractice action are done away with. Only those physicians who have been through that experience can fully appre-

ciate how advantageous would be a prompt and private determination.

The question has been asked as to whether or not a physician insured under the group plan is covered against an adverse decision of the Grievance Committee upon a dispute between him and his patient. Where a patient and a physician agree to arbitrate a difference which, but for such arbitration, would have been the subject of a malpractice action, and where, upon the submission of such a controversy the Committee on Grievances orders the payment of a sum of money, such an order or decision would stand upon the same footing as a judgment of a court rendered upon a verdict of a jury in a malpractice suit. That is to say, if a patient and a physician agree to arbitrate such dispute and the award goes against the physician, the physician is covered by the group plan of insurance in precisely the same way as he would be covered were the dispute determined by a court instead of the Committee on Grievances.

The more the Medical Practice Act of 1926 is read, considered and applied, the more will it win the approval and confidence of both the medical profession and the laity. The Medical Society of the State of New York may well congratulate itself upon having written into the statutes of this State a thoroughly modern, comprehensive and enlightened law.

## FRACTURE OF ELBOW—WORKMEN'S COMPENSATION

The defendant in this action was a physician specializing in surgery. In the course of his practice patients were referred to him by an insurance company covering workmen's compensation risk. The plaintiff while engaged in his occupation as a painter fell from a ladder sustaining an injury to his arm. He was referred to a physician for treatment who attended him for a period of time. The condition of the arm not improving X-rays were taken of the injured arm which did not disclose any evidence of a past or present fracture. Another set of X-rays were subsequently taken which were likewise negative. The employee continued to complain of the injury to his arm and was finally referred to the defendant for treatment. After examination the defendant performed an operation removing some fibrous tissue in the region of the elbow. No evidence of fracture was found at this time. After the operation and treatment by the defendant the patient still continued to complain of the condition of his arm and he was then referred to another physician who found that he was well able to extend and flex his arm and found no evidence or signs of fracture. The patient still continuing to complain of his injury was referred to another physician who found no pathological condition, but a slight atrophy in the right triceps. His complaints con-

tinuing, further X-rays were taken of his arm which were reported negative. The insurance carrier having provided all of this medical treatment for the patient and having paid him workmen's compensation during the period, refused to make any further payments. The patient then presented a claim against his employer before the Workmen's Compensation Commission. He also instituted an action of alleged malpractice against the defendant surgeon, it being claimed that a piece of bone had been broken in the patient's arm which the defendant surgeon had failed to discover and remove and that the patient would have to submit to another operation for the removal of the same. Awards having been made to the plaintiff under the Workmen's Compensation Law for the injuries which he had sustained, in the answer of the defendant to the malpractice complaint an affirmative defense was pleaded of the making of the awards and payments to the plaintiff under the Workmen's Compensation Act.

The action continued on the calendar for some period of time. The plaintiff failing to prosecute the same, upon motion made on behalf of the defendant, the complaint was dismissed, terminating the action in the surgeon's favor.

## THE CHIROPRACTIC HEARINGS

Two hearings by the legislative committee to investigate chiropractic were held in New York City, December 2 and 23, 1926

The chiropractors presented additional arguments along about the same lines as those in the first two hearings reported on page 85 of the January 15 issue of this Journal

The committee has also held two additional hearings at which the opponents of chiropractic were heard, one in Albany on Thursday, February 3d, in the capitol at Albany, and another the next day in the Aldermanic Chamber, New York City

The Albany hearing was in charge of Dr Harold Rypins, Secretary of the Board of Medical Examiners. He introduced physicians with the intention of showing four points

- 1 There is no scientific basis for the claims of the chiropractors
- 2 Their educational standards are far too low
- 3 The fundamental necessity in treatment is diagnosis, a knowledge of which chiropractors do not have

- 4 Chiropractic is a menace to public health

The first witness was Dr Rypins himself who told of his investigation of chiropractic in 1924 and 1925 at the suggestion of his chief, Dr Augustus S Downing, Director of Professional Education. He had read all the chiropractic books in the State medical library, 129 in number, and all the journals of chiropractic, 5,026 in number. He had visited the National School of Chiropractic in Chicago, and the Palmer School in Davenport, seen their equipment and attended their classes. He investigated them in the same way that he investigated medical schools in the course of his official duties. He had also talked with many chiropractors and got their views regarding the foundations of chiropractic. Dr Rypins said that he had written his observations in a report which he filed with the Committee, but he gave a resumé of the fundamental principles of chiropractic as he had found them stated in the books and schools, and described by B J Palmer, the founder of the cult. Dr Rypins said that chiropractic was essentially a system of faith healing which resembled Christian Science in many ways. The chiropractors have a theory of a universal intelligence which Christian Science advocates call a Universal God. The intelligence or God activates every action of the body and mind. It enters the body by way of the brain, flows down the spinal cord and out through the nerves, and returns to the brain by other nerves. Sickness is the result of the failure of the universal intelligence to pass through to the brain and nerves. Christian Scientists say the blocking of the force occurs in the brain or mind, chiropractors say it occurs at the points where the nerves leave the spinal column. The Christian Scientists say "set the mind right and sickness ceases." The chiro-

practors claim to secure the same result by "releasing" the nerves from pressure

Mr Otis, counsel for the committee, said that the chiropractors were not claiming that faith entered into their treatment, but Dr Rypins replied that B J Palmer claimed it and so stated it to him, and he also said that faith was impressed on every student and that every chiropractor present in the room would recall that fact. Palmer insists that graduates of his school explain the theory of transmission of divine energy to their patients

Dr Rypins said that the faith of both the students and the patients was visualized by the "neurocalometer," which is a sensitive electric thermopile. The theory of action of the instrument is that its needle is deflected by the flow of divine energy along the nerve, while actually it indicates differences of temperature. A reading is taken with the instrument over a vertebra, an adjustment is made and another reading is taken which is nearly always different from the first because the manipulations have produced a slight change in the temperature of the skin, but the patient is immensely impressed with the movement of the needle and his faith is correspondingly elevated

The second witness was Dr Matthias Nicoll, Jr, Commissioner of Health of New York State. Dr Nicoll said that chiropractors acknowledge that they practice medicine and treat contagious diseases, although they know little about them and say they have no need to study them, yet failure to recognize them and treat them properly is not only harmful to the patient, but is also a public menace. Dr Nicoll also said that the State Department of Health is supervising 2,000 children crippled from poliomyelitis, many of whom were still almost helpless because they were improperly treated by chiropractors during the early stages when improvement might be effected

In closing Dr Nicoll expressed the hope that the committee will not recommend anyone to be licensed to treat the sick unless he is fitted to practice medicine

Dr Augustus S Downing, Deputy State Commissioner of Education, in charge of professional education, certified that he could not find any evidence of any scientific basis for the chiropractic treatment of diseases, although he had investigated it from many angles and during many years. Dr Downing exhibited the catalogues of several chiropractic schools and showed that practically no preliminary educational qualifications are required. He also showed a catalogue of the National School of Chiropractic of Chicago, in which is outlined a correspondence course leading up to a "Diploma" in chiropractic. Many chiropractors are practising on the basis of these diplomas. If the holder of a diploma attends the school for three months residence, he gets a

for many years, and his honor which comes to him, I think, most of us abrogate to ourselves. Of course, Phillips deserves it, but we put Phillips there, or Phillips put us in a position where we could put him there. I feel that a new era of prosperity for the profession is coming in with this presidency which gives us all as much personal as well as professional pride and joy."

Dr Gordon Berry, President of the American Federation for the Hard of Hearing, spoke on behalf of a delegation from his organization which was present. Speaking of the practical work of the Federation, Dr Berry said

"There are many hard of hearing children in our schools, nobody knows how many. We have taken it upon ourselves first to try to discover by a survey something about them, how many there are, and right away we discovered that some short and accurate means of testing the hearing must be devised. The Federation was able to interest the Bell Telephone Laboratories of the Western Electric Company, and they have finally produced an otometer which can test children in groups of forty at a time, and it takes about fifteen minutes to test those forty. By this and similar means over 20,000 children have now been tested and we can report with a fair degree of accuracy that from eight to twelve per cent of all school children under high school age have a notable impairment of hearing which means from 3,000,000 to 5,000,000 children in this country.

"I am happy to say that largely through Dr Phillips and the New York League's efforts, your city is now planning a city-wide investigation of the hearing of the school children. Then the impaired and handicapped cases must be investigated, treated in clinics, and given special educational advantages. How else can we systematically combat and prevent deafness?

"Dr Phillips must look with a great deal of pride on such a record."

Dr David Chester Brown, speaking for the Trustees of the American Medical Association, reviewed the work of Dr Phillips as Trustee of the Association since his appointment in 1917, and of his intense activities during the World War and afterward, when he was made President of the Trustees. Dr Brown also reviewed the great growth in the activities of the Trustees since 1917, so that instead of one meeting annually, meetings are held monthly, and much time is required of them in the intervals between the meetings.

The principal address was given by the Reverend Harry Emerson Fosdick, D.D., Pastor of the Park Avenue Baptist Church, which Dr Phillips attends. Dr Fosdick spoke on the debt of religion to science. This address expresses the point of view of the scientific physician so clearly that it is published in full on page 173.

Dr Phillips, in making the closing address of the evening, said that "Friendship" is the word that has gone through his mind during the evening. "I can call almost every man in this audience by his first name," he said, "and when we meet in private conversation, we call each other by our first names. This means a great deal, and is one of the reasons that I can use that word 'friendship' tonight.

"There has been a good deal said about these offices that I have held, but perhaps I can tell you a little secret about some of those offices. I appreciated the honor when I was made President of the Medical Society of the County of New York. It was a great honor. But to me the honor was immediately turned into a job, and when I was made President of the New York State Medical Society, that honor was fully appreciated, but that honor was turned into a job. When the presidency of the great American Medical Association came, marvelous honor that it is, that honor was turned into a job. And so it has been throughout all my life. I love to work, and it is that love of work that has been one of the secrets of some of these things you have learned about tonight.

"There is another thing that has to do with us in our lives, and I have been blessed with it probably by birth—a joyous optimism. I haven't much use and never did have much use for the pessimist. That hopeful nature that God gave me is one of the great secrets of the happy life which I have led."

In closing, Dr Phillips quoted Kipling's poem which well expresses the aspirations of himself and his friends.

"When Earth's last picture is painted  
And the tubes are twisted and dried,  
When the oldest colors have faded  
And the youngest critic has died,  
We shall rest, and, faith we shall need it—  
Lie down for an aeon or two,  
Till the Master of All Good Workmen  
Shall put us to work anew.

"And those that were good shall be happy,  
They shall sit in a golden chair,  
They shall splash at a ten-league canvas  
With brushes of comet's hair,  
They shall find real saints to draw from,  
They shall find Magdalene, Peter and Paul,  
They shall work for an age at a sitting  
Work and never be tired at all!

"And only the Master shall praise us,  
And only the Master shall blame,  
And no one shall work for money,  
And no one shall work for fame,  
But each for the joy of working,  
And each in his separate star,  
Shall draw the thing as he sees it  
For the God of Things as they are!"

Mr Oliver filed the detailed reports of the investigations with the Committee. This ended the hearing in Albany.

The hearing of the Committee was resumed on the morning of Friday, February 4, in the Aldermanic Chambers of the City Hall, New York City. Dr William A. Cutter, Dean of the Post Graduate Medical School, was the first witness. He said that he had investigated the chiropractic schools of New York City at the request of Dr. Downing, Director of Professional Education for the New York State Regents. He had found the schools poorly equipped, and the instruction poor. The New York College of Chiropractic, for example, was conducted in a former dwelling house at 245 West 72nd Street. The basement was used as a clinic for patients, the first floor, as offices, the bedrooms on the second and third floors, as classrooms, and the fourth floor as sleeping quarters for the teachers. Yet the school claimed to have an enrollment of 400 students.

Some chiropractic schools were granting degrees without authority from the Regents, and one was giving the degree of Doctor of Philosophy.

As a result of the investigation, the managers of two schools were prosecuted by the District Attorney, and convicted of violation of the laws.

The question was asked "Assuming proper chiropractic schools exist, would you say that chiropractic was a proper subject for legislation?" The answer was "There is no need for a new law."

Concerning the preliminary education required for entrance into the schools, Dr. Cutter said that the catalogue requirements were "A high school education or its equivalent", but the equivalent that was accepted was merely the ability to read and write.

The catalogues of the chiropractic schools required 2,000 hours of instruction during the course, but actually the lectures were curtailed and often omitted.

Dr. Louis I. Harris, Commissioner of Health of New York City, said that the Department received dozens of complaints from laymen every year about chiropractors who were treating contagious diseases, such as polomyelitis, diphtheria, scarlet fever, typhoid and venereal diseases, to the injury of the patients and the menace of the public. The complaints were not merely of failure to report the diseases to the Department, but also of actual harm done to the patients.

When Dr. Harris was asked if he had instituted prosecutions against the chiropractors, he said that he had given the evidence to the District Attorney, and that few or no prosecutions were undertaken.

Dr. Harris said that his Department was not concerned with the question as to what group should treat the sick, but that the Department

does expect all healers to recognize communicable diseases, and to take measures to control them. While doctors can use any form of treatment, the burden is equally upon all to make correct diagnoses, and to be allies of the Department of Health. A chiropractor does not recognize communicable diseases, for he denies their bacterial origin and the necessity of recognizing bacteria, and he has not been trained in the bedside recognition of the diseases. He is therefore an opponent of the Department of Health.

The counsel for the Committee again proposed the question of a lame back to be treated with rubbing. Dr. Harris said that a masseur might perform a manipulation which the patient asked for, but neither the masseur nor a chiropractor had a right to make a diagnosis. A lame back, for example, might be caused by a sarcoma, or tuberculosis, or an aneurism, or high blood pressure, or impaired kidney, and in any of these conditions, rubbing might do harm. If chiropractors were merely masseurs, their business would be gone. They demand the right to make diagnosis.

Dr. Harris said there was no need for a new legislation. Let the chiropractors study to know diseases as a doctor does, and do not give the benediction of the law to those who are not qualified.

Dr. Harris was asked a number of questions concerning the advisability of recognizing the chiropractors with certain restrictions, such as that of requiring them to report communicable diseases, to which he replied clearly and concisely, giving the point of view of the physicians.

When Dr. Harris was asked about the mentality of the public, and the ability of the people generally to tell a good doctor from one unskilled, he said, "I would not disparage the public, but the people are not fitted to judge of any one's ability to build a bridge or do any other scientific work, medicine included."

Mr. George J. Nelbach, secretary of the Committee on Tuberculosis and Public Health of the State Charities Aid Association, said that he was detailed by his organization to come before the Committee and to present its attitude toward chiropractic laws. In 1920, when the legislature passed a law legalizing chiropractors, the State Charities Aid Association had made an investigation of the claims of chiropractors, and, as a result, had decided to adopt an attitude of active opposition to the legal recognition of chiropractors on the ground that they were a menace to public health.

Mr. Nelbach said that his organization was spending much time and money in order to instruct the people about scientific medicine, and that much of their efforts would be wasted if the people could get efficient treatment from unqualified persons.

Dr. James E. Sadlier, of Poughkeepsie, president-elect of the Medical Society of the State of

doctor's degree On this Dr Downing commented "You can see the absolute insufficiency of the training to qualify anyone to deal with the human body"

Dr Downing also exhibited the applications of several chiropractors who wished to register as physio-therapists These men gave their educational qualifications and made them appear as high as possible Dr Downing gave examples of the education these men claimed One applicant from Batavia had attended the National College of Chiropractic in Chicago for six months and received the degree of doctor "The title of doctor when given by a University indicates that the recipient is a learned man and has given quite a period of time to the intensive study of some particular branch," said Dr Downing "Yet this man exploits the title of doctor after a brief study and with no evidence of a preliminary education"

A man in Wolcott got a title of doctor after three months' study in the New Jersey College of Chiropractic A man in Niagara Falls got a diploma in the National School after three months' study and has practiced chiropractic ever since A man in Buffalo attended a school one month and does not say that he ever received even a diploma and yet he has been a practitioner of chiropractic A man in Buffalo attended the American College of Chiropractic for three months and got a certificate of dissection, and also in the same time received a certificate of proficiency in X-ray and spinography

"I have never opposed the practice of homeopathy, eclecticism, osteopathy or chiropractic as such," said Dr Downing, "but I have insisted that anyone who practices any form of healing shall have the education necessary to understand the disease and the body of the patient, and the action of the therapeutic agencies which he applies"

Dr Downing also said that the chiropractors seem willing to accept high educational standards for all who will enter the practice in the future, provided a waiver clause was inserted permitting those now engaged in the practice to continue The waiver clause cannot be accepted by the Regents for it is wrong in principle

Dr James F Rooney of Albany, when asked by the counsel for the Committee if a medical doctor ever needed the assistance of a chiropractor, said that he never knew of such an instance He said that he based his objection to the recognition of chiropractors on two points 1, it was not founded on science, and 2, it is a menace to the public in that it denies the modern conception of contagious diseases He cited diphtheria and smallpox as examples of diseases that are controlled by vaccines and serums, which chiropractors say are not needed Answering the chiropractors' offer to report contagious diseases, Dr Rooney showed the impossibility of recognizing them without long scientific training

Dr Frederick Parsons, Commissioner of the State Department of Mental Hygiene, told of the impractical nature of the theory of chiropractic, and said that the spinal column was extremely thick and tough, and that to get into it at autopsy was extremely difficult, even with a hammer and chisel It was therefore almost impossible to move the vertebrae by means of manipulations with the fingers or hands

Illness does not follow the logical order of text-book descriptions Serious diseases may have slow, insidious onsets when fatigue and pain may be the principal symptoms Tuberculosis patients for example, go to their doctors to get tonics for tired feelings To diagnose the condition requires a skillful examination, with probably an X-ray photograph and a bacterial examination of the sputum To neglect these means of diagnosis and delay in the treatment is unfair to the patient, the relatives, and the community The condition is similar in cancer, heart disease, and diabetes

Dr Parsons also described the effective prevention of outbreaks of diphtheria in state hospitals by means of toxin-antitoxin, in contrast with the ineffectiveness of preventive measures based on examinations of the throat and isolations and quarantines

In closing, Dr Parsons referred to the mental capacity tests used in the Army during the World War, and said that they showed that the average mental age of the troops of the whole Army was thirteen and a half years At least one-third of the people have the mental capacity of thirteen-year-old children, and to them any doctor appears as good as another The intelligent man knows a good doctor when he sees one The State has a duty to perform for the unintelligent to certify that a doctor is competent when it gives him a license to diagnose and treat disease

Dr Parsons was asked by the Counsel of the Committee "Suppose I come down from Albany on a sleeper and get a lame back Ought not I have the privilege of getting it rubbed by a chiropractor?" The doctor answered "If a chiropractor can rub your back, why can't he rub your neck for a sore throat?"

Mr Robert Oliver, attorney for the Medical Society of the State of New York, said that in 1921 the counsel for the Society had investigated chiropractic by examining books on the subjects and submitting their statements to skilled physicians for opinions He also sent six fourth-year medical students from Bellevue to the chiropractic clinics The students were first examined physically, and X-rays were taken of their spinal columns, both before and after the investigations

The students consulted chiropractors for pretended ailments One said he had pains in the front of his foot, and another, eye trouble Both received spinal manipulations, and neither showed the least change in their spinal cords

## THE COMMITTEE ON PUBLIC RELATIONS

The Committee on Public Relations, whose appointment was announced on page 81 of this Journal for January 15, held its first meeting on the afternoon of January 27 in the Waldorf-Astoria Hotel. Those present were

From the State Society Drs Cottis, Britt, Townsend, Farmer, Fisher, and Lawrence

From the Committee on Tuberculosis and Public Health of the State Charities Aid Association, Mr Folks, Dr Farrand, Dr Wisskotten, Mr Nelbach, Dr Munger substituting for Dr Lindsley R Williams, and Mr Burritt, substituting for Mr John A Kingsbury

Dr Cottis was chosen permanent chairman of the Joint Committee, and Dr Lawrence, secretary

Mr Homer Folks opened the conference by stating the desire of those representing the lay organizations to avoid overlapping of activities and misunderstandings in objects and methods

Dr Lawrence stated that it was the policy of the leaders of the Medical Society of the State of New York to confer with laymen and organizations which are willing to enter into conferences with the representatives of the medical profession

Dr Livingston Farrand said that the leaders in all successful public health activities had been physicians, but that these medical leaders had been far in advance of the ideas of the conservative rank and file of medical organizations

Dr Farrand described the situation in Tomp-

kins County in regard to the County Health Unit and said that the County Medical Society had discussed the matter at its last meeting (see this Journal, November 15, 1926 page 953). While there may be a sufficient number of influential laymen and physicians in Tompkins County to persuade the Board of Supervisors to authorize a County Health Unit in the near future, yet the cause of public health in the County would advance more rapidly if time were taken now to inform the physicians regarding the proposed unit and to begin formal action with the endorsement of the County Medical Society

After considerable friendly discussion of the misunderstandings that had occurred in the past, particularly over the subject of County Health Units, the Committee voted to appoint a sub-committee to study the question of organizing those Units and report back to the Joint Committee in regard to three points, namely 1, the exact meaning of the present law covering Health Units, 2, the arguments pro and con, and 3, the best procedure to be used in establishing such Units, in case they appear to be desirable

The Committee appointed consists of Dr Farmer, chairman, Dr Britt, Dr Lawrence, Mr Homer Folks, Mr Nelbach and Dr Williams

It was decided that a meeting of the sub-committee should be held on the afternoon of February 9 in New York City, and that the Joint Committee should meet on February 24 in the Onondaga Hotel, Syracuse.

---

## MEDICAL LEGISLATION

Very little that is news is developing in medical legislation. The bills which have been introduced are almost identical with those of last year. The optometrists seek permission to use the word "doctor" when followed by the words "of optometry." They seek to capitalize the title of doctor without qualifying themselves in such a way that they may be considered learned within the scientific meaning of the word

Laws have been introduced modifying state aid to municipalities doing public health work, even to the largest cities. The season is too early to determine who their sponsors are and their definite intentions

The Committee on Legislation of the State

Medical Society sends out a weekly bulletin to the county committees. This will contain news of legislation as fast as it develops

The members of the Public Health Committees of the Senate and Assembly are as follows.

Senate Webb, Chairman, Dutchess, Baumes, Orange, Thayer, Franklin, Mastick, Westchester, Hickey, Erie, Wicks, Ulster, Carroll, Kings, Love, Kings, M J Kennedy, New York

Assembly Dr Lattin, Chairman, Orleans, Esmond, Saratoga, Austin, Monroe, Lyon, Cayuga, Loomis, Delaware, Van Cleef, Seneca, Barnhardt, Erie, Trepamer, Clinton, Watson, Cattaraugus, Cline, Kings, Doyle, Kings, Grossman, New York, Cantor, New York

New York, said that early diagnosis was essential in treating many diseases, such as cancer and tuberculosis. To make the diagnosis early required years of scientific study. To delay diagnosis meant ultimate death. He had seen many persons whose diseases became incurable because of a delay in diagnosis. Chiropractors could not make early diagnoses—no one can without long study under expert teachers.

Asked concerning the value of a knowledge of chiropractic in addition to medical knowledge and skill, Dr. Sadlier said that he had never heard that such a knowledge was ever of any value to a physician in diagnosis or treatment.

Miss Sarah Ahearn, a detective from the Police Headquarters, New York City, was the last witness. She gave testimony concerning her visits to chiropractors in order to take treatments for

pretended diseases, and as a result the District Attorney had served summons on twenty-five chiropractors for violating the laws forbidding the practice of medicine without a license. She said that the chiropractors made diagnoses of her condition, took money for treatments, and said they could help her provided she paid in advance for courses of treatment. The chiropractors were careful about their promises to cure her completely, because they were aware that detectives were on their trail, and to fail to cure after a promise to do so constituted a breach of contract.

The Committee announced that it would begin to hold executive sessions during the week beginning February 7 in order to discuss the evidence and to formulate its report, which must be made before March first.

# DIPHTHERIA

*can be Prevented!*

**Toxin-Antitoxin**  
*protects Babies and Children*

**See your Doctor or Health Officer**

### OUTDOOR PANEL POSTER

Utilizing the best methods of modern publicity, the cooperative State-wide Diphtheria Prevention Campaign, which has just completed its first year in New York State, outside of New York City, is sending out a diphtheria prevention message on the outdoor poster panels throughout the state, in the form of the miniature reproduction given below.

The poster in attractive colors was specially prepared for this purpose and has received the approval of the Medical Society of the State of New York, through its representatives on the joint committee sponsoring the campaign.

This medium of reaching the parents of little

children has been made possible through a generous gift on the part of the New York State Outdoor Advertising Association of free poster space throughout the state with no charge for the service of caring for and putting up the posters. The posters themselves are being utilized in various counties as the contribution of the Local Committees on Tuberculosis and Public Health of the State Charities Aid Association.

The showing of these posters will undoubtedly arouse still further interest in diphtheria prevention and will contribute to the steadily increasing number of children who become immunized.

## THE COMMITTEE ON PUBLIC RELATIONS

The Committee on Public Relations, whose appointment was announced on page 81 of this Journal for January 15, held its first meeting on the afternoon of January 27 in the Waldorf-Astoria Hotel. Those present were

From the State Society Drs Cottis, Britt, Townsend, Farmer, Fisher, and Lawrence

From the Committee on Tuberculosis and Public Health of the State Charities Aid Association, Mr Folks, Dr Farrand, Dr Wisskotten, Mr Nelbach, Dr Munger substituting for Dr Lindsley R Williams, and Mr Burritt, substituting for Mr John A Kingsbury

Dr Cottis was chosen permanent chairman of the Joint Committee, and Dr Lawrence, secretary

Mr Homer Folks opened the conference by stating the desire of those representing the lay organizations to avoid overlapping of activities and misunderstandings in objects and methods

Dr Lawrence stated that it was the policy of the leaders of the Medical Society of the State of New York to confer with laymen and organizations which are willing to enter into conferences with the representatives of the medical profession

Dr Livingston Farrand said that the leaders in all successful public health activities had been physicians, but that these medical leaders had been far in advance of the ideas of the conservative rank and file of medical organizations

Dr Farrand described the situation in Tomp-

kins County in regard to the County Health Unit and said that the County Medical Society had discussed the matter at its last meeting (see this Journal, November 15, 1926, page 953). While there may be a sufficient number of influential laymen and physicians in Tompkins County to persuade the Board of Supervisors to authorize a County Health Unit in the near future, yet the cause of public health in the County would advance more rapidly if time were taken now to inform the physicians regarding the proposed unit and to begin formal action with the endorsement of the County Medical Society

After considerable friendly discussion of the misunderstandings that had occurred in the past, particularly over the subject of County Health Units, the Committee voted to appoint a sub-committee to study the question of organizing those Units and report back to the Joint Committee in regard to three points, namely 1, the exact meaning of the present law covering Health Units, 2, the arguments pro and con, and 3, the best procedure to be used in establishing such Units, in case they appear to be desirable

The Committee appointed consists of Dr Farmer, chairman, Dr Britt, Dr Lawrence, Mr Homer Folks, Mr Nelbach and Dr Williams

It was decided that a meeting of the sub-committee should be held on the afternoon of February 9 in New York City, and that the Joint Committee should meet on February 24 in the Onondaga Hotel, Syracuse

# THE DAILY PRESS

## ROGER BACON'S ELIXIR OF LIFE

The newspapers have found an exceedingly human story in the account of the translation of the principal Lath work of Roger Bacon, by Dr Robert Bell Burke, Professor of Latin in the University of Pennsylvania. Dr Burke has translated Bacon's *Opus Majus* which was written on the invitation of Pope Clement in order to supply the head of the church with a compendium of the scientific knowledge of his day. The particular passages which have received notice in the daily press are those relative to the elixir of life, which was supposed to confer immortal youth upon its user.

Roger Bacon was born in England in the year 1214 and was highly educated in all branches of the knowledge of his time. He was a Churchman as were all the educated people of his time, and like some other scholars, possibly many, he knew all that was contained in the available books of his day. His greatness lay in the fact that he put their information to experimental test. He was the pioneer of modern research. He is credited with the invention of gunpowder in its modern form. He investigated the laws of light, and described the eye from actual dissections of the organ. He was far in advance of his time and was the close friend of the priest who afterward became Pope Clement, and encouraged his investigations and writings, but was imprisoned by Clement's successor as a dangerous subverter of the existing order of the world. He continued to write in an obscure form in which was concealed a cypher which was recently solved.

The New York *Herald Tribune* of February 1 contains extracts from Dr Burke's translation of that part of the *Opus Majus* which deals with the elixir of youth. Bacon quotes Aristotle as saying "God has prepared a means and a remedy for tempering the humors and preserving health and for acquiring many things with which to combat the ills of old age, and to retard them and to mitigate such evils, and has revealed these things to his saints and prophets. There is a medicine called the ineffable glory and treasure of philosophers which completely rectifies the whole human body."

Bacon says that the formula of the medicine was revealed to Adam and his sons, and then he goes on to quote clinical examples of its effects as recorded in the writings of the ancients. He quoted examples from Atephins and Pliny. A later writer, he said, told of a plowman who turned up a bottle filled with skysen, which renewed his youth and vigor. Another man was recorded as

having found an oil which he rubbed over his whole body except the soles of his feet, and was renewed in his flesh excepting his soles which mortified so that he had to ride. He also quoted the example of another man who lived for several centuries because of a substance which he had prepared for a great king, but which the king wished him to try first on some ignorant person.

Having proved by clinical records that a life of centuries was possible, Bacon told of the formula of the elixir, which was described in the writings. This he said, was composed of 1, that which is tempered to the fourth degree, 2, what swims in the sea, 3, what grows in the air, 4, what is cast up by the sea, 5, a plant of Judea, 6, what is found in the vitals of a long-lived animal, and 7, the two snakes which are the food of Tyrians and Ethiopians. Bacon then goes on at some length to show that the first ingredient is gold, the second, pearl, the third the flower called sea dew, the fourth ambergris, the fifth the aloe tone, the sixth a bone growing in a stag's heart.

Bacon says that the Tyrian snake is an excellent remedy for the corruptions of old age if it is eaten with things suitable for one's constitution and condition as is taught in the book of the regimen of the aged.

The Ethiopian snake is the dragon referred to by David in the Psalm which reads "Thou hast given it as food to the tribes of the Ethiopians." Bacon then goes on to tell how hunters lure the dragons from their lairs, bridle and saddle them and ride them to exhaustion in order to make their flesh tender. "Those who use the flesh prolong life and sharpen their intellect beyond all conception, for no instruction that can be given by man can produce such wisdom as the eating of this flesh, as we have learned through men of proved reliability on whose word no doubt can be cast."

This is an example of Bacon's writings. He at least quoted the best histories attainable, which is the modern method. After all, Bacon could not be expected to experiment with every theory and prove every alleged fact of which he read. Concerning this point the New York *Sun* of February 2 says editorially:

"The wonder is not that he retained a few of the superstitious beliefs of his time, but that he rejected so many. He stood at the threshold of experimental science. He is said to have expended 2,000 pounds sterling in study and experiment, a sum enormous in a period when craftsmen of the highest skill were glad to work for four pence a day."

A comparison of the beliefs of Bacon's day with those of ours is made in an editorial in the *New York Herald Tribune* of February which says

"Roger Bacon's formula for an elixir of life will seem humorous to an age which knows that pearls and Tyrian snakes are no aids to longevity, but it was only a day or two ago that our own Voronoff was urging his hopes for a race of supercentenarians supported by an adequate monkey population. An improved scientific equipment

has enabled Voronoff to abandon Tyrian snakes in favor of the monkeys, but the objects seem to be the same. In the intervening space of seven hundred years we have done much, yet we are still near enough to him to want elixirs. We still regard our doctors as magicians, and try their remedies on 'the ignorant' and we would probably start monkey farms as cheerfully as Bacon's contemporaries might have started Tyrian snake houses in the same sort of faith."

---

### A PLAGUE OF MICE

The newspapers during the month of January have carried news stories about a plague of mice in Kern County, California. The *New York Sun* of January 28 says that 30,000 acres of old lake bed, now dried up and devoted to grain, is overrun with mice which have exhausted the available food and are migrating in droves to new areas. Mr. S. E. Piper, government expert, said that three varieties of mice are found: 1, the white-footed mouse; 2, the ordinary house mouse; and 3, the big California meadow mouse, which is by far the worst pest of all.

The hordes of mice were first noticed about Thanksgiving time, and they appeared again in the middle of December and of January. In the meantime birds and animals of prey appeared in numbers and materially aided the farmers in destroying the pests.

The *New York Sun* of January 28 also explains the situation in an editorial entitled "Let nature do it." It says

"Stockmen and farmers of the West are organizing to oppose the Federal and State warfare on the coyote on the ground that it is one of the best friends of the desert dwellers. Experienced ranchmen in some parts of California declared that coyotes kept within bounds other pests that

were more troublesome than coyotes ever were. If Kansas had not been so industrious in killing off the coyote it would not have had so many plagues of long-legged rabbits.

"The extermination of the coyote would permit the smaller vermin, rats, ground squirrels and rabbits, to develop into a serious menace. Whenever the number of coyotes is seriously diminished, plagues dangerous to mankind break out among the too numerous rodents.

"People are beginning to learn that nature, uninterfered with, maintains a balance of power, and that it is perilous to disturb that balance."

The sequence of events in Kern County may be readily seen. The drainage of the lake, the destruction of the natural refuge of birds and beasts of prey, an abundant supply of mouse food and a tremendous increase in the mouse population unhindered by its natural enemies, the overpopulation of mice, their migration, and finally the influx of their natural enemies which will restore a normal balance of wild life in the region—provided man is wise enough to let the birds and beasts fight out their own destinies.

This balance of life in nature is of special interest to physicians in view of the reported infection of rodents with the plague bacillus.

---

### THE ROORBACK

Campaign lies are sometimes circulated for political purposes, and doctors have been known to be threatened with exposures of alleged indiscretions in order to influence their action in regard to patients, especially psychiatric cases. Doctors who are threatened with those stories may take courage from a decision recently given in England, that to circulate a malicious story constitutes libel.

The two sons of William E. Gladstone resented the action of a newspaper writer in printing alleged stories of Gladstone's immoral relations with women prominent in society and on the stage. There being no direct redress, the sons took the deliberate course of calling him a foul-mouthed

liar and cur in public, thereby provoking him to sue the sons for libel. The court decided that the sons were entirely correct in applying the epithets.

The *New York Sun* of February 3 comments editorially on a bill introduced in Congress providing severe punishment for any one who circulates an attack on a candidate within a fortnight of election unless he first furnishes the candidate with a copy of the story.

Campaign lies and threats of vile implications against doctors are all of the mold. Any doctor who is threatened in that way will do well to accept the challenge boldly and openly, and then sue its instigator at once.

# BOOK REVIEWS

**PSYCHOLOGICAL MEDICINE.** A Manual on Mental Diseases for Practitioners and Students By SIR MAURICE CRAIG, M.A., M.D., and THOMAS BEATON, M.D. Fourth edition. Octavo of 437 pages, with 25 plates. Philadelphia, P. Blakiston's Son and Company, 1926. Cloth, \$6.00.

This book is the fourth edition of a work that first appeared in 1905. It is based on an experience gained from a large private and institutional practice. It is well balanced. There is an excellent summary of the elementary psychological principles underlying human behavior. The psychoses are treated quite exhaustively, and the anatomical changes as well as the psychopathological dynamics in these disorders are lucidly presented. The psychoneuroses are likewise treated in an authoritative manner. There is a chapter devoted to the relationship of insanity with the law. The book is a valuable one, it is highly recommended.

IRVING J. SANDS

**STUDIES IN INTRACRANIAL, PHYSIOLOGY AND SURGERY.** The Third Circulation, The Hypophysis, The Gliomas. By HARVEY CUSHING, M.D. Octavo of 146 pages, illustrated. London and New York, Oxford University Press, 1926. Paper, \$3.25. (Oxford Medical Publications.)

The Cameron Prize Lectures, delivered by Dr. Cushing at the University of Edinburgh in 1925, are much more than highly scientific treatises concerning the subject matter involved.

They give the most recent authentic information about these highly important members of the intracranial family, facts which are in large part as essential to the well informed medical man of today as to him in specialized activities of this sphere.

They are written in the clear, concise, yet comprehensive style characteristic of this investigator and practical brain surgeon, who occupies a unique place in his chosen field.

This little group of lectures is a classic which could be used to distinct advantage in medical schools to clear up the misconceptions taught about the subjects covered, reclassifying the known facts and eliminating fallacies.

The author thus summarizes on the cerebro-spinal fluid—"The Third Circulation"—which gives a glimpse of the scope of this lecture. "Thus we have seen whence the cerebro-spinal fluid takes its origin, how it comes to make pathways for itself by percolating through the primitive mesenchyme, how these pathways which originate from cells of the neural crest become lined with a specialized mesothelial membrane, and how minute outlets for the absorption of the fluid into the large venous channels are formed—in short how this circulatory switch for a fluid peculiar to the ventricular and meningeal spaces comes into existence and how it communicates with the deeper parts of the brain by perivascular tubes of the pia-arachnoid."

In dealing with the physiology and pathology of the pituitary gland, Dr. Cushing refers to its inter-relation to the other ductless glands and the medical man who may be naturally endowed with investigative talents, could well ponder over this field for further effort after he reads the author's opinion that present day surgery of the hypophysis is practically in the "stone age" of its development! The third lecture on, "Intracranial Tumors and the Surgeon," covers practical phases of this subject by a master-workman who has no peer.

The valuable and practical observations set forth in these lectures have an added interest when it is recalled

that the author is fourth in direct line of medical ancestry of distinction.

H. G. DUNHAN

**ELEMENTS OF PATHOLOGY.** By ALLER G. ELLIS, M.Sc., M.D., Octavo of 544 pages, with 95 illustrations. Philadelphia, P. Blakiston's Son and Company, 1926. Cloth, \$5.00.

In this work an attempt has been made to crystallize out from the huge mass of information pertaining to pathology those simple fundamentals which are the old standbys in that science.

The writer endeavors to steer clear of all but well established facts in order that the beginner in this subject starts with a clear cut conception. Although the work is by no means complete, the purpose of the author has been well carried out. In fact, it has been done to such an extent that in some places the facts have been stripped of all embellishments remaining but skeletal in character.

To medical students the book should prove to be a valuable asset since the facts that it contains can be used as definite starting points from which broader view points can be developed as they broaden their studies in pathology.

MAX LEDERER.

**RHEUMATISM, Its Meaning and its Menace.** By LEWELLYS F. BARKER, M.D. and NORMAN B. COLE, M.D. 12mo of 165 pages. New York, London, D. Appleton and Company, 1926. Cloth, \$1.50.

This is one of a series of books on health subjects written for the non-medical public. Rheumatic Fever is stated to be the greatest menace to the heart health of children and adolescents. The confusion associated with the name "Rheumatism" is explained and the term as denoting a single definite condition is discarded. Instead, the rheumatic diseases are discussed under the headings of acute rheumatic fever, chronic infectious arthritis, so-called primary chronic progressive polyarthritis, so-called primary hypertrophic osteo-arthritis and gout. From eighty to ninety-five per cent of heart trouble in young people is stated to be due to rheumatic fever.

The book will prove useful to the intelligent layman who wishes to acquire a general knowledge of these diseases.

W. E. McCOLLUM

**A MANUAL OF PROCTOLOGY.** By T. CHITTENDEN HILL, Ph.B., M.D. Second edition, thoroughly revised, 12mo. of 294 pages, with 101 illustrations. Philadelphia and New York, Lea and Febiger, 1926. Cloth, \$3.50.

This book appears as a second edition revised by the author with an additional chapter by Dr. R. C. Coffey on "The Radical Operation for Cancer of the Rectum."

Many of the present day writers of text-books on rectal disease seem to attempt to make large books. To do so, they often insert illogical and irrelevant opinions of others which require additional pages. All of these insertions become tiresome to the reader, and also detract from the personal responsibility of the author. This book has none of these objectionable features.

Dr. Hill's book is the epitome of what a manual on proctology should be. He has described, in a clear, concise and pleasing manner, all of his subjects. The book can be accepted as an excellent treatise on the different forms of rectal diseases most commonly seen by the general practitioner.

MARTIN L. BODKIN

**THE SURGICAL TREATMENT OF GOITER** By WILLARD BARTLETT A B, A M, M D Octavo of 365 pages, with 130 illustrations St Louis, The C. V Mosby Company, 1926 Cloth, \$8.50

The object of this monograph is to present a study in detail of the problems involved in the surgical treatment of goiter. This naturally embraces a thorough knowledge of the disease, a proper estimation of the individual patient, and the logical indication for surgical intervention, and, of course, an intelligent selection of the proper operation suitable to the particular patient.

The clinical side of the disease, however, is constantly kept in view, as is evidenced by the addition of a chapter on the heart in goiter, by Dr Samuel J Grant, by the chapter on unusual manifestations in goiter, which are essentially manifestations of disturbed functions of the thyroid gland, as is further brought out by the emphasis of the importance of aftercare of the patient, which is in line with the thoughts of the author that the thyroid is only a part of a complex condition. Particularly significant is the statement, that

"The ultimate success in this branch of surgery is attainable only when one contemplates in every thyroid patient the individual as a whole rather than concentrates on the goiter alone, though it may for the moment obtrude itself as the most conspicuous of the many interdependent components now thoroughly out of balance."

One is impressed with the thoroughness of the author in the preparation of this work, his broad concept of the disease, and his high regard for the opinions of others, and especially the respectful and almost reverent tone in which he so frequently refers to the pioneers in this field of surgery.

HERMAN SHANN

**ENZYMES, Properties, Distribution, Methods and Applications** By SELMAN A. WAKSMAN, M.S., Ph.D. and WILBURT C. DAVIDSON, M.A., M.D. Octavo of 364 pages Baltimore, Williams & Wilkins Co., 1926 Cloth, \$5.50

In this book of 350 pages the authors have reviewed very thoroughly the literature of enzymes of which they enumerate about sixty, and have arranged the facts thus obtained in a connected and readable form. They state that they have consulted over two thousand references mostly in the original papers. This represents an immense amount of work. Not only so, but they include in their Bibliography, 1,323 references to original papers, which are referred to by number throughout the text, as authority for nearly every statement made.

The book is thus an authoritative treatise on practically all known facts relative to the occurrence, methods of isolation or preparation, properties and action, products and uses of the enzymes.

The subject matter is arranged under four general headings. The first four chapters, 57 pages, dealing with the General Properties of Enzymes. The second group of three chapters, 60 pages, on the Distribution of Enzymes. The third group of seven chapters, 130 pages, deals with the Methods for the Preparation and Study of Enzymes. The fourth heading is the Practical Uses of the Enzymes in the arts.

This is followed by a bibliography of references to original sources of information, and a very complete index. As a work of reference on the subject of the enzymes it is an admirable book, and it is to be highly recommended.

E. H. B.

**WHY INFECTIONS? In Teeth, Tonsils and Other Organs** By NICHOLAS KOPELOFF, Ph.D., 12mo of 182 pages 16 illustrations New York and London, Alfred A Knopf, 1926

The author tackles a problem similar to "Why We Behave Like Human Beings." Just why we have infections in the teeth, tonsils, and other organs remained unexplained at the end of the book, just as the reason we behave like human beings is unanswered at the end of the book by Dorsey.

The doctor discusses disease to the tune of nine chapters as sort of a stepping stone to chapter ten. He lays particular stress on the so-called focal infections, as he goes along. On arriving at the tenth chapter the reason for the book being written will be found, and from there on the doctor shows his intentions to the reader. If a reader is bored by the first nine chapters, he may skip them, and turn to chapter ten, and begin.

The book was written to call attention to people that the wholesale eradication of infected or suspected infected organs for the cure of a great many diseases of which the etiology is unknown has not led to much benefit to mankind. Each subject is discussed cautiously and there is no element in this book of dogma. You ask to be shown, and you are told just how much can be promised. As most doctors have learned, who really analyse their cases properly, the theory of focal infection is much overdone. It is the exceptional patient that is cured by operations on so-called focally infected organs.

If another edition of this book is published, it is to be hoped that the early part of the book will be much abridged, and the latter part extended.

J ARTHUR BUCHANAN

**PLASTIC SURGERY OF THE HEAD, FACE AND NECK.** By H Lyons Hunt, M.D., L.R.C.S. Octavo of 404 pages, illustrated with 342 engravings and 10 colored plates Philadelphia and New York, Lea and Febiger, 1926 Cloth, \$7.00

This four hundred page monograph shows what can be accomplished when one, who is master of his subject, endeavors in a careful and conscientious way to give his experience for the benefit of others.

He analyzes the skin for color, texture, moisture and age, makes preliminary plaster models when necessary, uses an oblique incision in a line of cleavage, avoids infection by careful operative technique and complete hemostasis, removes sutures early and puts powdered turtle bile on the wound and exposes it to sunlight and fresh air.

In 7000 operations there were only two cases where the wound failed to heal by first intention.

The chapter on Local Anaesthesia is by S. R. Maxeiner and Physiotherapy in Superficial Surgery of the Face by Sinclair Tousey. All the chapters are good but the one on Keloids is especially interesting and valuable.

Any surgeon will profit by reading this book before performing any plastic operation on the head, face or neck.

HENRY F GRAHAM

**A TEXTBOOK OF THE PRACTICE OF MEDICINE.** By various authors Edited by Frederick W Price, M.D. Second edition Octavo of 1828 pages London and New York, Oxford University Press, 1926 Cloth, \$10.00 (Oxford Medical Publications)

One's interest in this work is stimulated by its dedication to that classical writer, Sir Clifford Allbutt and by its handy size and compactness. The use of a thin paper makes the volume comparatively small for the large number of subjects covered in the eighteen hundred and twenty-eight pages.

Among the contributors are some of the best known men of England, as W Langdon Brown, Sir Thomas Horder, Theodore Thompson and James Collier. The style, in general, is pleasing as is the case with many of the British writers. Generally a whole section is allotted to one author or to two writing in collaboration.

The work is extensive in scope and covers in addition to Internal Medicine, the fields of Neurology, Psychological Medicine, Diseases of the Skin and Tropical Diseases. The inclusion of these subjects makes the book very handy for reference.

In reading various sections, one discovers nothing with which to find fault. It is undoubtedly one of the best single volumes on the Practice of Medicine.

W. E. McC.

# OUR NEIGHBORS

## HEALTH MERGERS

The subject of group treatment in distinction to private practice is discussed in the following editorial from the January issue of *California and Western Medicine*

"The extensive creation of mergers, financial, industrial commercial and what-not, are among the most significant movements of recent years. The chief new or recent feature of the idea is the name merger, which suggests that a name may have something to do with the odor of a rose

"Another recent feature of the merger movement is its increasing application to matters of health, sociology, relief, charity, thereby introducing elements calculated to influence the very foundation of society and affect profoundly every individual

"The philosophy of mergers is the same, whatever the field of endeavor, and they are therefore worthy of serious study, particularly when they invade established human-service occupations

"The heart of any merger is centralized, more or less autocratic control, and while this may, and doubtless often does, insure advantages in material matters, it may not follow that it will be equally efficacious in dealing with those moral, social and charitable attributes which are inherent in individuals, which are in a state of flux and may not be measured in material terms

"Unquestionably, well conceived and intelligently conducted mergers, whatever the field covered, may reduce waste, duplication of effort, and thereby increase the purchasing power of the dollar, stabilize and standardize production and change competition between individuals to group competition, or even replace competition by price-fixing methods. There are examples all about us in mergers of many classes and sizes that supply ample evidence of this fact, encouraging so far. However, when mergers enter the field of sociology, health, and other human services heretofore peculiarly personal, other and vastly more

difficult problems arise. It may be possible even here to save dollars by standardizing the treatment of frailties, infirmities and shortcomings of mankind en masse and serving them through mergers also standardized, but what of the individual? Can we succeed in pouring into a common hopper operated by organized effort, service, and the blessed spirit of service, that is an inherent individualized quality of man, and grinding out stereotyped relief to meet the highly individual needs of others with safety?

"'Health' mergers, to be more specific, are prominently to the fore, and they are proceeding apace from merger to supermerger—at least on paper and in the intent of sponsors. Extensively mergerized health, medical, social, and spiritual welfare, doubtless would simplify giving and serving and insure at least a steady income and regular hours, to those who serve. It would reduce the matter of support to paying taxes or writing a check to the merger periodically—but would it not also tend to simplify life for the supplicants and beneficiaries? In this respect the results of the 'dole' and the consequences of mergerized medicine in certain countries is illuminating, and there are interesting lessons closer home that may be studied with profit

"It has been postulated and confirmed by experience that many human-service needs, the most crying ones, are too highly personal to be met by other than individual service, in the rendering of which both parties receive something that enriches life, encourages thrift, self-reliance, hope, faith, and charity. While these virtues are sublimated by individual contact even by groups with common feelings and purposes, they may not blend well in the mills of mergers, and we might do well to carefully study the subject before we endorse current trends too wholeheartedly"

## COUNTY SOCIETY PROGRAMS AND ACTIVITIES

*A County Society Calendar* The plan of "A Minimal Program for a County Society" discussed in an editorial in the December fifteenth issue of this Journal, is further discussed in the December issue of the Journal of the Michigan State Medical Society in an editorial entitled "A County Society Calendar." The editor, Dr. F. C. Warnshuis outlines a concrete program embodying the principal features of the minimal program. The editorial reads

"County medical Societies by virtue of the position they occupy are obligated to conduct an extensive program of activity which directly affects the membership of the Societies and indirectly the community. In order that the obligation of each society may be met and accomplishment recorded it is recommended that societies consider the activities and plans of work herewith attached, which cover the activities in

## The Management of an Infant's Diet

# Mellin's Food—A Milk Modifier

## Constipation

It is common observance among physicians who use Mellin's Food as a modifier of milk for infant feeding that their baby patients are seldom troubled with constipation, and if this annoying symptom does occasionally appear it is easily corrected by increasing the amount of Mellin's Food in the daily mixture or by some other slight readjustment of the formula

Some fault in the arrangement of the food formula is practically always the cause of constipation, so it seems logical to overcome the difficulty by rearranging the food elements to a more perfect balance rather than to employ medical means, which at best afford temporary relief only

In a pamphlet entitled, "Constipation in Infancy", the common causes of constipation are set forth for the physician's consideration, also practical suggestions for their correction. All of the matter presented is based upon observation extending over a long period and will prove of good service to every physician interested in the subject.

A copy of the pamphlet will be sent promptly upon request. Samples of Mellin's Food also if desired.

## BULLETIN OF THE MEDICAL SOCIETY OF THE COUNTY OF KINGS

*Editorial Note*—The Bulletin of the Medical Society of the County of Kings for January, 1927, carries an article on the examination of persons in whom tuberculosis may be suspected—and the possibility of its presence must always be in the mind of the medical examiner. Yet no other disease is more frequently overlooked. Why? Probably the very triteness of the subject.

However, the Medical Society of the County of Kings is using its monthly Bulletin to remind the members concerning the common symptoms and signs which suggest the disease. The article follows.

### PERIODIC MEDICAL EXAMINATIONS OF APPARENTLY HEALTHY PERSONS

#### PRACTICE PRECLINICAL MEDICINE IN YOUR OFFICE

Pretuberculous conditions belong in the field of every day medical practice. Your patients need your guidance in health. Periodic physical examinations, preventive measures, prescribed hygiene, postponed disability help to eliminate tuberculosis.

Tuberculosis has a particular relation to the periodic examination of apparently healthy persons.

The reduction of the tuberculosis morbidity and mortality has been due in the last analysis, to early recognition through adequate physical examination of signs of disease in patients coming under medical care—with a presenting symptom.

*The Next Step*—If all we know about the disease is applied, if it be true that all infection occurs in early life, if we all have it, if proper adjustment to environment (job, play, sleep, exercise, diet, fresh air) will keep our tuberculosis from developing—then the next step in health guidance and hygienic regimen based upon knowledge gained as a result of a real physical examination plus periodic re-examinations.

*The Symptoms—Pre-protuberculous*—Be especially alert to sense the importance of persistent tired feeling, "lack-of-pep," "frequent colds," "more or less constant indigestion," slight losses of weight or persisting underweight, increasing nervousness or irritability of disposition, enduring hoarseness or huskiness of voice,—whenever these occur, make still more searching your examination of the lungs and if the result is negative, have it confirmed by radiogram—for these are leads to the early recognition of Pulmonic Infiltration.

# OSCODAL

## Palatable Cod Liver Oil Therapy in Tablet Form

OSCODAL is a palatable cod liver oil concentrate containing the essential principles of the oil—the fat-soluble vitamins—with the following advantages:

- (1) Elimination of objectionable bulk, nauseating odor and unpleasant taste
- (2) Accurate dosage
- (3) Every lot is physiologically standardized
- (4) Oscodal is readily taken
- (5) Oscodal is acceptable at all seasons

OSCODAL is marketed in bottles of 100 tablets.

# SALIPYRIN *Riedel*

Is a chemical combination of anti-pyrin and salicylic acid. The therapeutic effects of both these components are preserved, although modified by close chemical union and in a very great degree deprived of the dangers of mechanical mixtures.

Salipyrin is distinguished from other salicylates

by the comparative freedom from ill-effects (absence of free antipyrin) and prompt antipyretic and sedative action.

**INDICATIONS** Influenza, Colds, Catarrh of the Nose and Throat, Rheumatism, Neuralgia, Alcoholic Excess, Pleurisy, Dysmenorrhea, Metrorrhagia, Vaginitis, etc. If given early in the attack, Salipyrin generally succeeds in aborting colds.

Salipyrin is supplied in powder form and as SALIPYRETS in tablets of  $7\frac{3}{4}$  to 15 grains each.

Approved by the Council on Pharmacy and Chemistry of the American Medical Association for inclusion with N. N. R.

**RIEDEL & CO., Inc.**

Berry and South 5th Streets, Brooklyn, N. Y.

These occurrences call for at least a suspicion of the presence of Latent Tuberculosis and should not be passed over until proven innocent. And right here—it is remarkable what the X-ray will pick up where a most expert physical examination will fail to reveal anything.

Look upon every case with a past history of—pleurisy (dry or wet), blood spitting (teaspoonful or more), or ischiorectal abscess with special suspicion.

Be loath to satisfy yourself with a diagnosis of "Neurasthena"—dig deeper—there is invariably some underlying cause.

**The Symptoms—Clinical Tuberculosis**—Every physician knows them—those of the so-called incipient stage and worse. The layman knows that long continued "bronchitis" is possibly tuberculosis. And that spitting blood, afternoon fever, night sweats, loss of weight, fatigue, etc., spells consumption. For such, preventive medicine is past—curative medicine may be of value—palliative medicine perhaps all that can be offered. Were every patient of every doctor in Brooklyn regularly examined could such cases develop among the examinees? And what would our town's tuberculosis rate be?

**The Physical Signs**—All physical signs are important,—especially the auscultatory,—more especially the recognition of fine and moderately coarse moist rales in the upper half of the chest,—most especially the method of eliciting these rales by use of the cough followed by deep inspiration and expiration.

**The Laboratory**—Let us not forget it. An expectoration lasting four weeks or more—resulting perhaps only from a slight "clearing of the throat" in the morning—may harbor clumps of acid-fast bacilli. But especially bear in mind that one Negative Report (and even ten Negative Reports) does not rule out the possible presence of Clinical Pulmonary Tuberculosis.

**The Next Step In Service**—Examine all patients thoroughly utilize all existing facilities, educational, recreational, occupational, clinical that Brooklyn affords. They exist for all classes—the public health committee will help you find them if you do not know them.

**The Library Is Tuberculosis Wise**—The last word in preventive medicine has not been written but the printed page for laymen, for doctors, for nurses, for health workers is on the library shelves for you and your patients to read. Have you looked up recently the writings of Krause, Lawason Brown, Bray, Miller, Fowler, Guy, Jacobs, Knopf, Fishberg, Myers, Kinghorn and Walters?

## UNUSUAL MANIFESTATIONS OF MALARIA

That the diagnosis of malaria covers a multitude of sins of omission is well known. It is not so common for malaria to be called by a wrong name. The January issue of the *Journal of the Medical Association of Georgia* contains the following article, describing malaria conditions which are mistaken for other diseases.

"That the malaria parasite is capable of causing a definite succession of characteristic symptoms is so well known as to need no elaboration. That the parasite often is the principal factor in causing atypical symptoms, as for example hemorrhagic or blackwater fever, is less well known except to those practitioners who live in malarial sections. That the parasite may produce many symptoms which masquerade under the guise of many types of other well known diseases has perhaps not been as much emphasized as other features of the great malarial problem.

"Because of the necessity of correct diagnosis as a guide to treatment, it is important to know in how unusual ways malaria may manifest itself.

"According to Manson, the following actual erroneous diagnoses have been made on purely clinical grounds without examination of the blood, but subsequently proven to be manifestations of infection with aestivo-autumnal (sub-tertian) parasites.

"(1) Cerebral forms. Sun-stroke or heat stroke, mental derangement, hysteria, alcoholism, aphasia, epilepsy and meningitis.

"(2) Abdominal forms. Dysentery-amebic or bacillary, intestinal obstruction, appendicitis, biliary colic, cholecystitis, hemorrhagic pancreatitis, liver abscess.

"(3) Pulmonary forms (Malarial pyrexia with pulmonary congestion and myocarditis). Bronchitis, pneumonia, valvular heart disease.

"(4) Cases with cutaneous petechia have been mistaken for measles, endocarditis and purpura.

"(5) Icteric cases have been confused with obstructive jaundice.

"(6) Cachectic cases have been diagnosed acute nephritis, pernicious anemia or tuberculosis.

"(7) Edematous forms. A general edema may be the only outstanding sign in heavy sub-tertian infections.

"The surgeon as well as the internist has need to bear in mind abdominal forms of malaria. Thus, Deaderick has emphasized the importance of differentiating these types from the so-called surgical belly and reports a case of tertian malaria simulating appendicitis.

"The relation of malarial infection to insanity is of decided interest. A T W Forrester has reported in the *London Lancet* interesting figures concerning this subject. He writes that in Macedonia, malaria was recorded as far and away the largest factor in the causation of mental diseases among British troops. He separates the cases into two groups. In the first group were placed the cases of insanity associated with a malarial attack itself, and in the second group those occurring as the result of repeated attacks."

## WHAT A FULL-TIME SECRETARY COULD DO

The February issue of the *Colorado Medicine*, the organ of the Colorado State Medical Society, has an article on what a full-time secretary could do for the Society. Problems differ in the several states and it is interesting to read what duties the Colorado Society would assign to its secretary. The article is as follows:

"What could a full-time executive secretary do besides the duties already required of our present secretary, which would improve our organization and make membership of more value to the individual?"

"Many State Societies have undertaken measures which this one has not considered practicable because no one officer can give the necessary time to the administrative features. Several movements which could be inaugurated may be mentioned:

### MEDICAL DEFENSE

"This is furnished by a number of State Societies, with plans varying from simple investigation of the merits of an active or threatening suit and provision for legal defense only, to the more comprehensive inclusion of full indemnity, covering the same grounds as the usual liability insurance policy. It works well in some states, not so well in others. One or two have undertaken it and later dropped it.

### COLLECTION AGENCY, CREDIT RATING BUREAU OR BOTH

"A plan for recording of delinquent debtors by a centralized bureau might eventuate as a valuable clearing house through which chronic dead-beats would be segregated from the simply unfortunate, with resulting protection to the doctor against the former and deserved consideration for the latter. If properly conducted with those two objectives, many of our members feel the plan would be desirable. Whether a collection agency in

connection would be appropriate is another question—at least some special arrangement with an independent collection agency might be made on a state-wide plan which through numbers would reduce the commission percentage."

### COLORADO MEDICINE

"An executive secretary of sufficient caliber should perhaps take over the business management of *Colorado Medicine* and be able to greatly increase the amount of advertising, as well as relieve the Editor of mechanical and other details which tend to detract from the quality of his strictly editorial work (present incumbent excepted)—a 'business editor,' who should strive to make the journal as nearly as possible, if not quite, pay its own way.

### ORGANIZATION IN CONSTITUENT SOCIETIES

"It goes without saying that only a man familiar with medical problems and procedures, or capable of familiarizing himself with them and of understanding the idiosyncracies of doctors, should be selected for the position. He could then be trusted to visit the various (in Colorado, scattered) constituent societies at more or less regular intervals, arranging for special meetings, providing special programs, keeping them in touch with organization problems and undertakings (e g periodic health examinations), and in other ways arousing their interest. If a man is paid to do certain work, he is apt to do it. If it is left to volunteers or committees who are actuated only by devotion to the undertaking or a sense of duty, that devotion may soon become luke-warm and the sense of duty be satisfied within a few initial efforts.

"Other opportunities of the Secretary to enhance the good of our Society, depending upon his initiative and capabilities, would undoubtedly present themselves."

## INFLUENZA AND NASAL IRRIGATION

Apropos of the now prevalent disease Influenza it is well to bear in mind that nasal irrigation is strongly indicated in the treatment of this trouble

The Nichols Nasal Siphon accomplishes this best because of its negative pressure (suction) action

Physicians have found it useful in evacuating the pus that accumulates in the nasal cavity, which if allowed to remain will oftentimes leave serious after effects. This is especially true of the sinuses

Nichols Nasal Siphon is the only device with which the patient can be treated at his home, this being absolutely necessary in the malady. Therefore the device should be given strong consideration. See advertisement, page xxi. Adv.

## THE QUICKEST WAY TO LEARN

"One picture is worth a thousand words" says the Chinese, and with this proverb daily experience agrees. Think of the striking clinical cases "once seen, never forgotten"! Imagine all the striking cases of years gathered into a series of pictures animated with motion. Realize, too, that motion pictures are actions and "actions speak louder than words." Medical movies have arrived. The American College of Surgeons recently said so at Montreal. The "Motion Picture Course in Proctology" was the first complete post-graduate course utilizing medical movies ever offered to the medical public. It was brought to your attention a little over a year ago through the columns of the *N. Y. State Journal of Medicine*. Since that time satisfied students from all parts of the United States have taken the course. Dr. J. F. Montague of the Rectal Clinic, University and Bellevue Hospital Medical College will be glad to send a reprint entitled "The Study of Rectal Diseases in America" to all those interested. Among other things, this describes the course mentioned on page xxiv of this Journal. Inquiries may be directed to him at 30 East 40th St., N. Y. City. Adv.

## BRAUN'S SNARETOME

Tonsillectomy may be a minor surgery, but it requires its men to cope with it and the instrument to perform it. It is only a few years since Dr. Braun's tonsillotome was given to the profession, but its merits are daily realized.

Combining the slider and the snare method, it incorporates the advantages of both with none of the faults of either. Results gained practically no hemorrhage, no trauma, applicability of the instrument to every type of tonsil—simple and easy technique are essential enough not to be overlooked. Sold by E. B. Meyrowitz Surgical Instruments Co., New York, N. Y. See advertisement, page xvi. Adv.

## ACCIDENTAL HEMORRHAGE WITH A REPORT OF 34 CASES\*

By GEORGE L BROADHEAD, M D, NEW YORK CITY

**DEFINITION**—When we speak of accidental hemorrhage, we refer to bleeding, externally or internally, which occurs during the last three or four months of pregnancy and which is caused by the premature separation of a normally implanted placenta

Holmes,<sup>1</sup> in 1901, published his report of 200 cases of accidental hemorrhage collected from the literature and described the condition to which he gave the name "Ablatio Placentae" as follows. When the placenta is situated above that part of the uterus which must dilate to permit the egress of the fetus and when the placenta is partially or wholly detached in pregnancy or labor before the second stage—a condition of premature detachment obtains

De Lee<sup>2</sup> prefers to use the term "Abruptio Placentae" There are many cases, naturally, which are on the border line between accidental hemorrhage and lateral placenta previa

**Variety and Frequency**—The hemorrhage may be entirely external, internal (concealed), or there may be bleeding both externally and internally. The amount of blood loss may be slight—moderately large—or the hemorrhage may be excessive and the patient quickly exsanguinated. In a large percentage of cases, the bleeding is entirely or almost entirely external. Goodell<sup>3</sup> in his paper published in 1870, gave the following classification of concealed hemorrhage

- a The blood accumulates behind the placenta
- b Blood escapes between the membranes and the uterine wall
- c Blood forces its way into the amniotic sac.
- d Blood collects in the uterus when the presenting part blocks all escape.

In regard to frequency of the condition Holmes estimated, on the basis of his figures and the statistics of the Chicago Lying-in Hospital, that accidental hemorrhage of pathological importance (slight amount of bleeding) occurred about once in 200 cases, while hemorrhage of clinical importance (moderate and large amount of blood loss) occurred once in 500 cases. At the Harlem

Hospital we have collected 34 cases of severe hemorrhage in a total of 16,500 cases, giving a ratio of about 1 485. In 1897 the author<sup>4</sup> published a paper on accidental hemorrhage in which he stated that in 5,900 cases at the Sloane Hospital, there were 57 mild cases, giving a frequency of 1 100. This series probably included many cases in which the bleeding was very slight, and of small clinical interest. With reference to absolutely concealed hemorrhage the total number reported by Holmes (including those cases reported by Goodell<sup>3</sup>) was 113. Of 306 cases reported by Goodell and Holmes, 193 showed external hemorrhage, or 63 per cent. In our series of 34 cases, there was no case of absolute concealment, although in 10 patients there was extensive concealed hemorrhage. Adding our series of 34 cases to the 306 cases reported by Goodell and Holmes, we find that external hemorrhage was present in 67 per cent of the cases. In our series the frequency of accidental hemorrhage in primiparae was 21 per cent, corresponding closely with Holmes' figures of 19.2 per cent.

### Period of Gestation when Hemorrhage Occurs

TABLE No 1

PERIOD OF GESTATION	
6½ Months	0
7-7½ "	3
7½-8 "	5
8-8½ "	8
8½-9 "	15
Unknown	3
Total	34
PARITY	
Primiparae	7
Multiparae	26
Unknown	1
Total	34

*Note* Seventeen of the multiparae had been pregnant five times or more, and of these eight had been pregnant from eight to eleven times

\* Read at the Annual Meeting of the Medical Society of the State of New York, at New York March 31 1926

This table gives the period of gestation in our cases when bleeding began. In 74 per cent hemorrhage took place during the last month of pregnancy—in 48.5 per cent during the last two weeks. Goodell quoted practically the same frequency, 50.5 per cent of bleeding at term, while Holmes quoted 33 per cent. In placenta previa the hemorrhage appears earlier in pregnancy, for while we find that in practically 50 per cent of patients accidental hemorrhage appears at or near term, in the series of 165 cases of placenta previa which have been collected by Langrock and the author,<sup>8</sup> only 35 per cent gave the first evidence of bleeding between 8½-9 months.

#### *Etiology, Pathology and Symptoms*

Among the predisposing and exciting causes of accidental hemorrhage we find toxemia of pregnancy, endometritis, blows, falls, sudden shock, a severe attack of coughing or vomiting, short cord, et cetera.

Holmes<sup>1</sup> believes that endometritis is the most frequent cause, as accidental hemorrhage occurs in multiparae in practically 80 per cent of all cases. In a series of 200 cases reported by Holmes<sup>1</sup>, 67 per cent gave a history of some accidental cause.

Toxemia of pregnancy is very frequently associated with the condition and, as we all know, is undoubtedly one of the chief causes. Williams<sup>2</sup> states that it is now recognized that in many of the severe cases the characteristic lesion occurs in the uterus which seems to explain not only the mode of origin of the separation, but also the failure of the organ to contract after being emptied. The uterus takes on a bluish, purplish, copper coloration and resembles an ovarian cyst with a twisted pedicle. The process may involve the tubes, ovaries and broad ligaments which are engorged with blood. In some there is extensive intramuscular hemorrhage which has so disassociated the muscular fibres as to destroy their contractile properties. Couvelaire<sup>7</sup> in 1911 designated the condition which has just been described, as uteroplacental apoplexy, of which Portes was able to collect 73 cases.

The symptoms of ablatio placentae are, bleeding and pain, either or both of which may be present. The blood may collect between the placenta and the uterine wall, causing pain and a moderate elevation of the uterus at the placenta site, or the blood may escape into the amniotic sac and remain concealed there, or, the blood may pass from the placenta site downward between the membranes and the uterine wall and thence through the cervix, the amount of blood varying from a slight quantity to an extremely severe hemorrhage. Associated with this external bleeding there may also be a variable amount of concealed hemorrhage. Instances of wholly concealed hemorrhage are very rare, as we have already stated earlier in the paper, but many of the severe

cases have both concealed and visible bleeding. When a considerable amount of blood is retained in the uterine cavity, the uterine wall becomes tense, hard, and tender, and it is no longer possible to palpate the fetus or to hear the fetal heart. It is worthy of note that the degree of shock in some of these cases is out of all proportion to the amount of blood loss, due, no doubt to the overdistention and hypertonicity of the uterus.

#### *The Prognosis and Mortality*

In the mild cases the prognosis is usually good, but in the really severe cases, the mortality for mother and child is very high, and must vary to a great extent depending upon the amount of blood loss, the amount of cervical dilation, the environment of the patient, and the promptness with which appropriate treatment can be carried out. Statistically it is difficult to give figures which can be compared with others for it is impossible to know in many cases, even approximately, the amount of blood which has been lost. Again, as we know, patients react very differently to the same amount of blood loss. Even though the life of the woman may be spared, severe blood loss weakens the patient and so lowers her vitality that morbidity, as well as mortality, must be taken into consideration.

Holmes<sup>1</sup> gives the maternal mortality in his 200 cases as 32.2 per cent. Goodell<sup>3</sup> quotes 50.9 per cent, Quigley<sup>4</sup> gives 80 per cent in severe cases, while in our series of 34 cases 9 women died, giving a mortality of 26.4 per cent.

The fetal mortality is very high, for prematurity and the amount of placental separation are vital factors. Goodell quotes 94.4 per cent, Holmes 85.8 per cent, while our series shows 85.3 per cent. In our 34 cases there were 27 still births, one baby, a monster, lived five minutes, one died in utero, the mother being undelivered, making a total of 29. Of the 5 babies born alive, and which were discharged in good condition from the hospital, 3 were full term, and 2 were at 8 months. The gross fetal mortality in the series is 85.3 per cent. In at least 13 patients, pregnancy had not proceeded beyond the eighth month, and maceration was present in at least 7 of the babies.

#### *Treatment*

The mild cases in which slight bleeding occurs during pregnancy should be put to bed and carefully observed. If the bleeding continues, a modified de Ribes bag should be introduced, followed by forceps or version if necessary. In some cases we have used pituitary extract in doses of 2-3 minims with great advantage. De Lee<sup>2</sup> states that accidental hemorrhage is the only condition in which he uses hypophysis before the uterus has been emptied. If bleeding occurs during the first stage of labor, a large size de Ribes bag should be introduced, delivery being completed

by forceps or version. We agree with Holmes<sup>1</sup> that, "the safest course is to protect the membranes until labor may be expedited." He believes that to keep the membranes intact is to retain intrauterine pressure. We also agree with Holmes that vaginal packing has no value which the hydrostatic bag does not possess and therefore should be discarded for the bag.

When a severe external or internal hemorrhage has occurred before labor, or in the first stage of labor, when the cervix is 1—2 fingers dilated, we have a choice of two methods of treatment—Cesarean section or the use of the de Ribes bag followed by forceps, version, or craniotomy. We are inclined to agree with Williams<sup>5</sup> that in these severe cases with little or no dilation and especially in primiparae, Cesarean section is the best procedure. If for any reason, section can not be done, the use of the de Ribes bag is strongly advised.

When the cervix is so well dilated that full dilation can be easily secured by slight manual dilation, this should be done and the delivery completed by forceps or version.

We are convinced that prompt Cesarean will save many women who would be lost by any other plan of treatment. Williams believes that Cesarean is the more justifiable because he maintains that when the uterine wall is infiltrated with blood and there are petechial areas under the peritoneum, hysterectomy is indicated. De Lee<sup>2</sup> also states that if hemorrhage does not immediately cease upon removal of the placenta, if the uterus remains flabby even with ergot and pituitin, and if there has been much manipulation, bagging, etc., a porro operation is indicated.

With reference to hysterectomy for the condition of so-called uteroplacental apoplexy, we do not agree that it is necessary to remove the uterus. Unfortunately in the one case in our series which showed the musculature of the uterus markedly hemorrhagic, the woman was admitted to the hospital in shock, having had a large hemorrhage at home and died on the table as the Cesarean wound was being closed. In this case, with or without hysterectomy the patient was doomed.

Recently, however, the writer saw a patient in consultation with Dr. E. G. Langrock of this city, and Cesarean was advised for concealed hemorrhage in a primipara with undilated cervix. The uterus showed the typical clinical picture described by Couvelaire, but the uterus was saved and the patient made a good recovery. Hysterectomy may be necessary where the uterus relaxes and bleeding continues in spite of packing. After the uterus has been emptied, whether by Cesarean or otherwise, we make routine use of the iodoform gauze uterine tampon, believing that there will be less blood loss following delivery. One c.c. of pituitin is given in every case also as a routine measure.

When hemorrhage has occurred in any pregnant woman, the patient's blood should be examined and typed, in order to be prepared for transfusion. At the present time we are transfusing more and more frequently with excellent results.

We have collected from the 16,500 records of the past 11 years at the Harlem Hospital, 34 cases of severe accidental hemorrhage, which gives us a relative frequency of 1 in 485 cases. The fact must be kept in mind that our hospital is a free city institution, where patients are frequently admitted as they are about to depart this life, and when it is too late for us to be of any help. The statistics of private cases, especially when the patients have had the advantage of confinement in a hospital, should show very much better results. A study of our ward cases will show that many of the patients were in poor condition from loss of blood, which had continued for hours and in many cases days, before admission to the hospital. We are convinced that had these women been treated promptly immediately after the initial hemorrhage, the figures would be very different.

#### *Cesarean Section*

Section was performed in 8 cases, the operation being done as a primary procedure in 5 cases and as a secondary procedure in 3 cases. In the five primary sections, one woman died on the operating table. The patient was admitted to the hospital in shock, with a history of an extensive hemorrhage at home. The musculature of the uterus was markedly hemorrhagic—and the woman died just as the wound had been closed.

In the secondary sections 2 women died. In these cases bags were used, but the patients grew steadily worse. One woman died 7 hours after section of shock, with no further bleeding, the other died of sepsis 4 days after operation. Earlier section might have yielded better results. The mortality in the 8 cases is 37.5 per cent, but in at least one woman the situation was almost hopeless from the start.

#### *Version*

This operation was performed in 10 cases, with 4 maternal deaths—40 per cent. All of the infants were still born. Four were macerated.

#### *Breech Extraction and Spontaneous Delivery*

There were 8 of these cases, with no maternal mortality—but 100 per cent fetal mortality. One of these patients was nearly exsanguinated in the second stage—and two showed extensive concealed hemorrhage.

Total maternal mortality in the 33 cases which received treatment was 24.2 per cent. As we have already stated, prompt treatment would no doubt have saved a number of lives, and greatly reduced the high mortality.

The method of delivery in our 34 cases is shown in Table No. 2.

### Maternal Mortality

There were, in the series, nine maternal deaths, of which a brief history will now be given.

*Case 1* Mrs D, a primipara, had been bleeding for nearly two hours before admission. The red cell count was 3,000,000, hemoglobin 65 per cent. A diagnosis of concealed hemorrhage was made, and a de Ribes bag was introduced. The uterus, however, became more distended, the patient grew weaker, and a Cesarean was performed. There was no further bleeding, but the woman died in shock, seven hours after the operation. Earlier section might have saved the patient's life.

*Case 2* Mrs G, a primipara, had been bleeding profusely before admission. A bag was introduced, but the uterus grew larger and Cesarean section was performed, the woman losing her life four days later of sepsis. Section immediately after admission might have given us a different result.

*Case 3* Mrs B, X Gravida, was admitted to the hospital in shock. The history was given of a large hemorrhage at home, 6—8 hours before admission. The uterus was tense, the cervix admitted one finger, and labor had not begun. The woman's condition was desperate, but Cesarean was done and the uterine muscle was found

to be markedly hemorrhagic. The wounds were rapidly closed, but the woman died on the table from hemorrhage and shock.

*Case 4* Mrs K. Unknown parity and period of gestation. The hospital record of the patient can not be located, and few details of treatment can be given. We know Podalic version and extraction were performed. The infant was a macerated still birth, and the patient died.

*Case 5* Mrs P, 3 Gravida, was admitted to the hospital in extremis, having had a profuse hemorrhage at home. The uterus was large and boggy, the cervix was thick and admitted 1½ fingers. While preparations were being made for Cesarean the patient died.

*Case 6* Mrs N, 8 Gravida, was pallid and pulseless on admission, the uterus was tense, tender and painful. The cervix was soft and three fingers dilated. After the cervix had been dilated manually, the membranes were ruptured and about 1500 c.c. of concealed blood escaped. The placenta was completely separated from its attachment to the uterus. Version and extraction were performed, but the woman died 2 hours later of shock and hemorrhage. In this case we believe that the result would have been the same even though Cesarean had been performed.

*Case 7* Mrs B, X Gravida, 7 months pregnant, was admitted to the hospital bleeding profusely. The woman was pale—pulse of poor quality—vertex above the brim. Cervix 1½ fingers dilated. Hick's version and extraction were performed and the uterus was packed, but the patient bled through the packing and died of hemorrhage 7 hours after admission to the hospital and 3 hours after delivery. The fetus weighing 3½ lb. was still born. Immediate section with or without hysterectomy might have saved the woman.

*Case 8* Mrs J, primipara, was admitted to the hospital at 11 P. M. The urine boiled solid and there were many casts of all varieties. The red cell count was 1,260,000, hemoglobin 30 per cent. The woman was stimulated, and at 11 A. M. of the following day a No. 4 de Ribes bag was introduced. At 4:30 P. M. the cervix was dilated slightly with the fingers and a low forceps operation was done. Two hours after delivery the patient died of hemorrhage. Although the woman's condition was very poor on admission, a Cesarean operation performed immediately might have saved her life.

*Case 9* Mrs R, 2 Gravida, was admitted to the hospital exsanguinated. The uterus was tense and painful, the cervix was almost fully dilated, the vertex presenting. The placenta had been completely separated and a large amount of concealed blood was present. Version and extraction were performed but the patient died 2 hours after admission. We had no reason to believe that Cesarean would have given a different result.

### Fetal Mortality

There were 27 still births, one baby lived five minutes, one died in utero, the mother being undelivered, making a total of 29

Of the 5 babies born alive, and which were discharged in good condition from the hospital, 3 were full term, and 2 were at 8 months

The gross fetal mortality in the series is 85.3% In at least 13 patients pregnancy had not proceeded beyond the eighth month, and maceration was present in at least 7 of the babies

In conclusion, we have tabulated the following brief clinical histories of our 34 cases, the study of which has been of great value and interest.

Case No	Parity	Period of Gestation	Treatment	Mother	Baby	Notes
1	IX	9	Abdominal Cesarean	Lived	Still Birth	Admitted to the hospital pulseless, almost moribund. Uneventful recovery
2	IX	7½	Abdominal Cesarean Uterus full of blood	Lived	Still Birth 4 4/16 lb	Admitted to the hospital in extremis
3	V	8½	Abdominal Cesarean Large amount of blood in the uterus	Lived	Lived 6 8/16 lb	Severe hemorrhage and bleeding at home for 12 hrs Not in labor Cervix closed R O A. above brim
4	I	8½	No 4 bag introduced but uterus enlarged and patient became worse Diagnosis concealed hemorrhage Abdominal Cesarean 12 to 15 ounces of blood in the uterus	Died	Still Birth 4 6/16 lb	Bleeding 1¼ hrs before admission to the hospital Uterus 8½ months size—tense. No fetal heart Cervix 2 F dilated Red cells 3,000,000 Hemoglobin 65% Died 7½ hrs after Cesarean from shock and previous hemorrhage No further bleeding in the hospital.
5	I	7½	Artificial rupture of the membranes No 5 bag introduced Increased tension in the uterus Abdominal Cesarean	Died	Still Birth Macerated	Profuse bleeding Cervix almost closed. Died 4 days later of sepsis
6	V	9	Abdominal Cesarean	Lived	Still Birth 4 4/16 lb	Admitted to the hospital pulseless (128 at the heart) Steady bleeding Uterus tender—tense Red cells 2,900,000 Hemoglobin 59% Mild temperature 10 days, then normal
7	II	7½	No 4 bag introduced at 2 A M Membranes accidentally ruptured (during introduction of the bag) 6 P M Abdominal Cesarean Placenta free in the uterus, ½ cupful of blood found in peritoneal cavity	Lived	Still Birth	Lost 1 quart of blood at home. Uterus tense—hard Not in labor No fetal heart or life felt Bleeding moderately Cervix 1 F dilated—rigid Hemoglobin 85% on admission
8	B X	7	Abdominal Cesarean Placenta free Uterine musculature markedly hemorrhagic. Rapid closure Died on table	Died	Still Birth	Admitted in shock Large hemorrhage and bleeding 6-8 hrs at home. Uterus tense and tender Cervix 1 F dilated. Profuse bleeding Not in labor Died 1½ hrs after admission
9	V	8	de Ribes bag introduced Breech presentation and extraction	Lived	Lived 5 6/16 lb	Hemorrhage profuse in first stage Cervix 1½ F dilated on admission.
10	?	?	Version and extraction	Died	Still Birth Macerated	Hospital record mislaid. Details unknown
11	III	8½		Died	Not Born	History of profuse hemorrhage at home Admitted in extremis Large tender, boggy uterus Cervix 1½ F dilated, thick. Head floating No fetal heart Died while preparations were being made for Cesarean, 1½ hrs after admission to the hospital.
12	VIII	8	Manually dilated (no bleeding) ruptured membranes 1500 c.c. blood in uterus Placenta free in the uterine cavity Version and extraction	Died	Still Birth 7 lb	Admitted to the hospital pulseless—pallid Uterus tense painful and tender No fetal heart, no life Cervix 3 F dilated—soft Head floating Died 2 hrs after delivery (2½ hrs after admission) Admitted to the hospital bleeding profusely—pale—pulse of poor quality Vertex above the brim Cervix 1½ F dilated Bled through packing Died 3 hrs after delivery—7 hrs after admission to the hospital
13	X	7	Hick's version—pituitrin Breech extraction	Died	Still Birth 3½ lb	
14	B IX	?	Spontaneous delivery (moderate hemorrhage)	Lived	Still Birth 6½ lb	Bleeding 2 hrs before admittance Abdomen tense—strong pains Cerv thick—2½ F dilated

### Maternal Mortality

There were, in the series, nine maternal deaths, of which a brief history will now be given

*Case 1* Mrs D, a primipara, had been bleeding for nearly two hours before admission. The red cell count was 3,000,000, hemoglobin 65 per cent. A diagnosis of concealed hemorrhage was made, and a de Ribes bag was introduced. The uterus, however, became more distended, the patient grew weaker, and a Cesarean was performed. There was no further bleeding, but the woman died in shock, seven hours after the operation. Earlier section might have saved the patient's life.

*Case 2* Mrs G, a primipara, had been bleeding profusely before admission. A bag was introduced, but the uterus grew larger and Cesarean section was performed, the woman losing her life four days later of sepsis. Section immediately after admission might have given us a different result.

*Case 3* Mrs B, X Gravida, was admitted to the hospital in shock. The history was given of a large hemorrhage at home, 6—8 hours before admission. The uterus was tense, the cervix admitted one finger, and labor had not begun. The woman's condition was desperate, but Cesarean was done and the uterine muscle was found

to be markedly hemorrhagic. The wounds were rapidly closed, but the woman died on the table from hemorrhage and shock.

*Case 4* Mrs K. Unknown parity and period of gestation. The hospital record of the patient can not be located, and few details of treatment can be given. We know Podalic version and extraction were performed. The infant was a macerated still birth, and the patient died.

*Case 5* Mrs P, 3 Gravida, was admitted to the hospital in extremis, having had a profuse hemorrhage at home. The uterus was large and boggy, the cervix was thick and admitted 1½ fingers. While preparations were being made for Cesarean the patient died.

*Case 6* Mrs N, 8 Gravida, was pallid and pulseless on admission, the uterus was tense, tender and painful. The cervix was soft and three fingers dilated. After the cervix had been dilated manually, the membranes were ruptured and about 1500 cc of concealed blood escaped. The placenta was completely separated from its attachment to the uterus. Version and extraction were performed, but the woman died 2 hours later of shock and hemorrhage. In this case we believe that the result would have been the same even though Cesarean had been performed.

*Case 7* Mrs B, X Gravida, 7 months pregnant, was admitted to the hospital bleeding profusely. The woman was pale—pulse of poor quality—vertex above the brim. Cervix 1½ fingers dilated. Hick's version and extraction were performed and the uterus was packed, but the patient bled through the packing and died of hemorrhage 7 hours after admission to the hospital and 3 hours after delivery. The fetus weighing 3½ lb was still born. Immediate section with or without hysterectomy might have saved the woman.

*Case 8* Mrs J, primipara, was admitted to the hospital at 11 P M. The urine boiled solid and there were many casts of all varieties. The red cell count was 1,260,000, hemoglobin 30 per cent. The woman was stimulated, and at 11 A. M. of the following day a No 4 de Ribes bag was introduced. At 4 30 P M the cervix was dilated slightly with the fingers and a low forceps operation was done. Two hours after delivery the patient died of hemorrhage. Although the woman's condition was very poor on admission, a Cesarean operation performed immediately might have saved her life.

*Case 9* Mrs R, 2 Gravida, was admitted to the hospital exsanguinated. The uterus was tense and painful, the cervix was almost fully dilated, the vertex presenting. The placenta had been completely separated and a large amount of concealed blood was present. Version and extraction were performed but the patient died 2 hours after admission. We had no reason to believe that Cesarean would have given a different result.

## THE DIAGNOSIS AND TREATMENT OF DISEASES OF THE THYROID GLAND\*

By ARNOLD S JACKSON, M D JACKSON CLINIC, MADISON, WIS

**T**HE subject of diseases of the thyroid gland covers such a large field that it is obviously impossible in a short paper to discuss any particular phase in detail. Consequently it seems that a general discussion will prove of greater interest than one limited to a single aspect.

Naturally goiter is the most important problem related to the thyroid gland and is the chief subject for discussion. While this disease does not appear to be as prevalent in New York as in some of our Middle Western states, yet its occurrence is so frequent as to merit the attention and careful study of every physician. The work that has already been done by certain members of your State Society has attracted national interest. So great has become the importance of this problem that governments, provinces, states and cities have appointed commissions to study means of checking the spread of goiter, and the fight has only begun. As in the case of cancer, science has accomplished more in attacking the disease than in discovering its etiology. The number of persons in this country afflicted with goiter is far greater than the number suffering from cancer and tuberculosis combined. Fortunately only a small proportion of those having goiter are suffering from a toxic condition.

Before entering further into this question, it seems best to review briefly a classification of goiter that will permit of a common discussion. The textbooks and medical schools have frequently been guilty of teaching such elaborate classifications as to lead to considerable confusion on this subject. The simpler the classification, the more easily may the various types be separated.

It is generally agreed that there is a simple, or non-toxic, and a toxic form of goiter. In the simple class are the colloid and the adenomatous forms. Until 1913 the toxic type was represented as exophthalmic goiter, but Plummer then distinguished between the latter and toxic adenoma. This classification gave two forms of toxic goiter, but European physicians and some in this country, notably the Crile school, have not accepted this distinction. They maintain that exophthalmic goiter and toxic adenoma with hyperthyroidism are a single entity. It seems obvious to me that there is a marked clinical and pathological distinction between these two types of toxic goiter. Moreover, I believe that a further differentiation should be made and a separate classification established for the group of cases of adenomatous goiter in which a toxic condition is induced by the injudicious

use of iodine. This toxic form of goiter was recognized by Kocher who warned against it. Because in many ways this condition resembled exophthalmic goiter, or Basedow's disease, Breuer called it "iodine Basedow." The literature contains the reports of many supposed cases of exophthalmic goiter induced by the indiscriminate use of iodine. Recently I reported a series of 50 cases in which hyperthyroidism had developed in this manner. Since this toxic state was always associated with adenomatous goiter and since the clinical symptoms varied markedly from those of either toxic adenoma or exophthalmic goiter, I felt that the term "iodine Basedow" was incorrect. Basedow's or Graves' disease is generally understood to mean exophthalmic goiter. Consequently I have proposed the term "iodine hyperthyroidism" as more truly suggestive of this condition.

Thus, to enumerate, we have the following types

- |                       |   |
|-----------------------|---|
| I Non-toxic or simple | { 1 Colloid<br>2 Adenomatous                                    |
| II Toxic              | { 1 Toxic Adenoma<br>2 Iodine Hyperthyroidism<br>3 Exophthalmic |

A few of the more important points about the various forms of goiter might be reviewed.

*Colloid Goiter Etiology* The majority of evidence, as shown by Marine and Lenhart in their experience in the prevention of goiter in animals and later in school children, suggests an iodine deficiency as the cause of simple goiter. The inverse ratio between the prevalence of goiter and the amount of iodine in the drinking water, as shown by McClendon, is further proof. As a result of this work millions of children in this country and in Europe are receiving iodine either under the direction of the state or their physicians. At present I have a group of seven hundred children between the ages of six and twenty under observation. While I am continuing to use and to advocate the use of iodine as a preventive of goiter, I regret that my experience in the treatment of many of these cases has been unsatisfactory. Two hundred patients have been carefully observed over a period of three years and the results of treatment, even in the younger patients, does not support the splendid work of Marine, Lenhart and Kimball. Possibly and probably iodine is successful in the prevention of colloid goiter in the majority of children. Once this form of goiter has developed, iodine is ineffective in many cases. For several years I have experimented, trying every form of iodine and various preparations of thyroid gland with only variable success. Probably iodine is what

\* Presented before the First District Branch of the Medical Society of the State of New York November 10 1926

15	I 8½	Nos 4 and 5 bags introduced Version and extraction (bleeding moderately) Blood clots in the uterus Fair condition	Lived	Still Birth 6¾ lb	Admitted bleeding slightly Abdomen tense and tender
16	I 9	Spontaneous, delivery Fair condition	Lived	Lived	Nearly exsanguinated II stage
17	I ? stant back pressure on the heart from large goiters, is an important factor in our mortality statistics. It is true that a certain number of persons with adenomatous goiters go through life and never suffer any consequences. From my observation and experience I do not advise my patients to take this chance.

**Toxic Adenomatous Goiter** An adenomatous goiter untreated will develop toxic symptoms on an average of twenty-five years after its appearance in about one out of every two cases. The onset of symptoms is so gradual and insidious as to be seldom observed by the patient for several years. Even after the patient reports to his physician to be treated for hypertension, heart trouble or Bright's disease, the presence of a small adenomatous goiter which is the focus of the trouble may be overlooked for some time. Advanced cases of this type offer a high surgical risk, and there is little that can be done either in the preoperative or postoperative care, that is of much benefit. Two years ago Plummer stopped digitalizing all these cases except those of broken compensation. He has felt that a lowered surgical mortality has resulted. Personally I have been hesitant about this step, although I am always ready to acknowledge the genius of Plummer. Iodine is not a factor except in the presence of an associated exophthal-

IV Same patient one month after operation. The relief of dyspnoea was almost immediate.

III Fortunately large adenomatous goiters as this seldom become toxic. The heart is damaged, however, by the constant back pressure.

mic goiter. When in doubt always administer iodine for a week, as in this short time no harm can result and trouble may be avoided. Auricular fibrillation is a frequent sequela. It is remarkable that, in some instances, within a few hours after operation the pulse becomes regular and remains so. In other cases the irregularity persists. If thyroidectomy is performed under local anesthesia the risk is materially decreased. Pneumonia and cardiac failure are complications not unlikely to occur in long-standing cases.

**Iodine Hyperthyroidism** The promiscuous use of iodine in the treatment of goiter as advocated by certain physicians, health authorities and persons of no medical knowledge whatever has greatly increased the incidence of this condition. In a series of 50 cases which I recently reviewed, I found that Lugol's solution of iodine administered by family physicians was responsible for six of the cases, including three that terminated fatally. Eight patients had been treated by the same physician. In seven cases patent medicines were the cause of the development of toxicity. It is impossible to review the clinical symptoms in this paper, but it is important to note that iodine should not be administered for more than three weeks to persons having adenomatous goiter after the age of twenty-one. Not every case will develop symptoms of iodine hyperthyroidism, but in

the body needs, but apparently it is not readily absorbed. Whether or not infection or other factors such as the water are concerned with the inability of the body to absorb iodine remains to be determined.

*Treatment* I am opposed to the wholesale distribution of iodine and believe it should be supplied to the school children only under the careful supervision of the health authorities or family physician. Certainly the most accurate and scientific method of treatment is the use of a chocolate tablet containing ten milligrams of iodine. This should be given once or twice a week during the school year, as indicated.

I. The majority of girls in the northern half of the United States have colloid goiters such as this. In the past such goiters have been considered as merely physiological enlargements. Iodine may prevent but will probably not cure this type.

*Non-Toxic Adenomatous Goiter Etiology Undetermined* Possibly this condition develops in a neglected colloid goiter as a form of compensatory hypertrophy. Probably the majority of these goiters arise during puberty and rarely if ever develop after the age of twenty-five. They are closely associated with the colloid type and probably develop in fully 50 per cent of these cases.

*Treatment* The administration of iodine to children in goiterous districts, from eight years of age on to twenty, may prevent the development of this form. Certainly once an adenom-

II Multiple non-toxic adenomas have grown rapidly in this colloid goiter. Surgery is indicated as a matter of protection for the future.

atous goiter has developed, all the iodine in the world will not remove the goiter, contrary to an idea that has been often supported. The goiter may decrease in size due to the absorption of colloid, but the adenomatous portion either becomes substernal or remains dormant, only to cause trouble perhaps in later years.

The use of iodine in small doses up to the age of twenty-one in the treatment of colloid goiters containing small adenomas is not objectionable, provided the patient is observed at frequent intervals. While the adenomatous portion will persist, the general enlargement of the goiter may be retarded so that a cosmetic success is achieved and surgery postponed.

After the age of twenty-one and occasionally before, I advise but do not urge the removal of adenomatous goiters as a matter of protection for the future. In probably 50 per cent, hyperthyroidism will ultimately result with consequent damage to the vital organs. A frequent cause of hypertension is toxic adenoma. In approximately 2 per cent malignancy will occur. Ten per cent will become substernal or intrathoracic and in time may involve the recurrent laryngeal nerves, or cause respiratory or cardiac embarrassment. Another 10 per cent will greatly enlarge and will become unsightly and prove a source of great discomfort and annoyance. Myocarditis, resulting from a con-

VII The same patient five months following operation for exophthalmic goiter. Recovery has been complete, the patient having regained her normal health and strength.

call attention to many important diagnostic points of differentiation, and an effort to do this will be made with the slides to be shown.

**Myxedema and Cretinism** These two diseases are, with the exception of goiter, probably the most important involving the thyroid gland. It

is well known that cretinism occurs wherever goiter is prevalent. The highest incidence of this condition is found in Switzerland. If we are to check the spread of this affliction in our country we must prevent the increase of goiter. Otherwise, after several more generations of goiter, we may certainly expect a marked increase of cretinism.

Myxedema may develop as the result of an infection that produces an acute or chronic thyroiditis and ultimate destruction of the gland. This may occur in untreated conditions or following a thyroidectomy. The characteristic symptoms of an increase in weight, a dry skin, loss of hair, retarded mental and physical effort are too well known to need discussion. Valuable contributory data may be obtained by a gastric test meal showing an hypochlorhydria and a blood test showing a secondary anemia. These patients may be treated for years as cases of chronic nephritis or myocarditis. Perhaps the most brilliant therapeutic result that may be observed in the realm of medicine follows the intravenous administration of thyroxin. Within a few hours the skin becomes warm and moist, there is a rapid loss of weight, the patient is no longer dull and lethargic, but again becomes active and alert both mentally and physically.

those who do, serious consequences may result

*Treatment* of these cases is, of course, prevention. Once symptoms have developed the drug should at once be withdrawn. Rest and symptomatic treatment may effect a medical cure. Surgery is indicated in the majority of instances and may be performed with considerable risk. Every effort should first be made to improve the patient's condition by medical measures.

*Exophthalmic Goiter Etiology* We are no closer to the solution of the etiology of this disease than we were a decade or two ago. Whether or not there is a predisposing constitutional factor, whether infection is important or whether some psychic stimulus from nerve strain or shock is important cannot be said. It is a fact that the disease is apparently increasing rapidly in this country and in greater ratio in the male sex. It progresses in series of waves of varying intensity, an unusually severe type appearing after the influenza epidemics. Its incidence seems to be related somewhat to the presence of colloid goiter, the two types occurring in a high ratio in the same districts.

*Treatment* Happily we have made remarkable progress in the treatment of this disease owing to the discovery by Plummer of the ef-

VI There are certain factors not indicated by the basal metabolic rate nor even the clinical symptoms that suggest a severe hyperthyroidism. The rate in this case was only plus 34 per cent.

V Case of iodine hyperthyroidism. The use of iodine in the treatment of adenomatous goiters may result in serious consequences. The B. M. R. in this case was plus 52 per cent. Operation resulted successfully, although performed with considerable risk.

ficacy of iodine as a preoperative measure. The long-drawn-out periods of hospitalization and consequent financial drain to the patient with the painful and often serious ligation and stage operations have been eliminated. I have used iodine in the preoperative and postoperative care of my patients for the past four years, and believe the surgical results achieved are largely dependent upon the use of this drug. Many patients admitted to the hospital in a crisis, that formerly might not have survived, respond remarkably to iodine. Patients come to the operating room quiet and composed and return to their rooms in the same condition. It is unnecessary to deceive the patient as to the time of operation, on the contrary, they are informed of the exact hour. The element of hyperthyroidism has been practically eliminated as a surgical complication, but this does not prevent the occurrence of pneumonia, cardiac failure or, perhaps most important of all, injury to the recurrent laryngeal nerves. In a previous article attention was called to the remarkable change effected in the pathology of the gland by iodine. There is a reversion of the hyperplastic gland to colloid so that operation is less tedious and difficult, the gland being neither as vascular nor as friable.

In this short paper it has been impossible to

The second epidemic to be described was one of influenza Dr Sherrill begins its description on page 20 as follows

"In the latter part of 1811 and the commencement of 1812, an unusual degree of health existed We had no fevers of any particular description, and few other diseases, until about February Cases of disease began to occur, somewhat novel in their appearance and progress, which operated with unusual force on the human system, and in many cases terminated fatally and unexpectedly It was no less than the commencement of a disease that called forth an exertion of the medical faculty, that excited much anxiety and solicitude in the community, and called upon its members frequently to witness its melancholy effects, and frequently to draw forth their sympathies or mingle their tears with bereaved friends or relatives, from bereavements of those who had fallen victims to the *winter epidemic*"

The doctor describes the disease as follows

"The case was generally ushered in with agues, or chills, which frequently continued an unusual period Generally, the longer time they continued the more obstinate was the case. Sometimes there was a sudden prostration of strength, and great want of action of the skin Frequently at the commencement, the patient was affected with violent pain in the chest, difficulty of breathing, pain in the head, back, and some one or all the limbs, and nausea, and puking of bilious matter Sometimes they were attacked with the usual symptoms of autumnal bilious fever, attended with a yellowness of the skin, yellow eyes, a yellowish tinge on the tongue, etc Sometimes the patient was attacked with dysenteric affection, together with pain, and some of the other symptoms noticed"

The epidemic seems to have almost disappeared during the summer, but it reappeared in the following winter Dr Sherrill says that the Rev L Birch of Stanford, who devoted the most of his time to calling on the sick, gave the number of deaths in his parish as follows

January	4
February	4
March	18
April	24
May	11
June	2
	63

He adds that the town has an area of 50 square miles, and contains 2,350 inhabitants

Dr Sherrill himself saw 112 cases during the second winter, of whom 7 died He says

"The disease again disappeared in 1813 on the approach of warm weather A very healthy summer and autumn ensued The train of the remittent bilious autumnal fever has been nearly

extinct since the appearance of the winter epidemic The summers and autumns in general have been healthy the winter and vernal seasons have produced some cases of disease, in addition to the ordinary diseases of the season, which assumed more or less the character of the epidemic, which may be considered sporadic cases of that disease."

Dr Sherrill devotes several pages to a discussion of the treatment of the disease He says

"The great business of a practitioner of medicine, at the appearance of numerous violent cases of disease, which he is called upon to alleviate, or conduct the suffering patient through, is to investigate the nature of it, to refer it to some general laws of morbid excitement, to observe the manner in which it produces its effects on the system, and to adopt some rational, and if possible, a successful method of cure Some time previous to the appearance of this disease among us, we had had numerous and various accounts of a complaint that had prevailed in several parts of the Eastern States with a good deal of violence and mortality Those accounts of the disease in the East, together with the method of treating it, were frequently contradictory, as they were brought to us by common intercourse and verbal communication, by newspaper intelligence, and by some professed medical publications The opinion respecting the nature of the disease to the Eastward, which was more generally held in this county, which was the most popular and generally received, was, that it was spotted fever from debility, or that it was a disease of a direct typhoid character, and that all evacuating remedies were injurious in the cure of it"

"When the disease first appeared, I did passively receive the doctrine that we had an epidemic of a direct typhoid character, and this was so much in accordance with popular opinion, that it required very considerable firmness to resist the current that set in from every direction against every species of depletion, hence nurses, old women, and uninformed individuals soon appeared with hemlocks, essences, cordials, and a vast host of heating sudorifics, the use of which was commenced with the commencement of the case, ready to lop off the heads of the hydra epidemic"

The doctor devotes 14 pages to a discussion of the best mode of treating the disease, and quoted numerous authorities from Sydenham to Dr Benjamin Rush, whom he calls the Sydenham of America He decided on cathartics and blood letting as the best He says

"The use of the lanert was commenced cautiously, particularly it was used in those cases where there was a pneumonia attack After bleeding an emetic was given, which was followed by a course of cathartic medicines so as to produce repeated and thorough alvine evacuations

## DISEASES OF DUTCHESS COUNTY A CENTURY AGO

By FRANK OVERTON, M D, PATCHOGUE, N Y

**D**R. JAMES E SADLIER, President-elect of the Medical Society of the State of New York, has run across a book entitled "A Review of the Diseases of Dutchess County from 1809 to 1825, being the subject of two addresses read before the Medical Society at their Annual Meeting in 1819 and 1825, also an essay on a disease of the jaw bones, to which is added an appendix containing notes and elucidations" by Hunting Sherrill, late President of the Dutchess County Medical Society

The book was published by S C Schenck, 252 Broadway, New York City, and printed by J Seymore, John Street It bears the date 1826, and a record that it was prepared in accordance with a vote of the Society, and the same vote requested to members to subscribe for the publication This record is signed by Calvert Canfield, Secretary, April 9, 1826

Dr Sherrill began the practice of medicine in Hyde Park, Dutchess County, in 1809 However, he is listed in a New York City Directory of 1842 as having an office at 8 Morton Street One of his other books records the fact that in 1859 he had a pharmacy at 513 Hudson Street He was a Homeopath and wrote an extensive treatise on "Homeopathic Practice of Medicine" in 1853 He also wrote a pamphlet called "Suggestions on Small Pox" in 1852, in which he advocated the use of a triturate of smallpox virus given internally In 1835 he published a pamphlet on the "Pathology of Epidemic Cholera" In 1859 he wrote a fifty-page pamphlet called "A Temperance Medical Lecture" All his writings were sane and sensible and do not show any leanings toward the partisan practice of medicine.

The first address in the Review of Diseases of Dutchess County describes the prevailing diseases which Dr Sherrill saw in the vicinity of Hyde Park during the decade 1809-1819 The first epidemic was one of severe malaria, concerning which he writes "In 1809, when I commenced the practice of medicine in this county, I found it very subject to fevers of the intermittent and remittent types, and in the autumn assuming symptoms of high bilious grades of disease Creek fever, and Hyde Park fever had become proverbial in this part of the country The same type of disease spread more or less through the county, particularly along the banks of Wappingers Creek, especially near the alluvial longs as you approach its source The disease obtained various local and popular names Still it was all remittent bilious fever and governed by the same general laws

"The vernal season opened with intermittent fevers of a mild character, and occasional remittents As the season advanced and the weather became warm, the intermittents became more se-

vere and obstinate, and the remittents increased in proportion to number as well as in severity Toward autumn and in the fall, real bilious remittents became very prevalent These frequently were attended with symptoms of great severity"

Dr Sherrill then describes the disease—rigors, restlessness, nausea, and severe pains in the head and back, and a yellow skin Dysentery symptoms were often present The cases often lasted two weeks, although, he says

"When the patient had early and proper attendance, the tendency of the disease was to intermit on the fifth, seventh, or ninth day and form a salutary crises"

The author continues "This was the constitutional character of the diseases during the summer and fall of 1809, 1810, and 1811, though there was less sickness in 1811 than in the preceding years, and those cases were of a milder grade. The remainder of those years were generally healthy, although there were more or less cases of phlegmasial disease, as catarrh, pneumonia, enteritis, croup, etc This period of 1811 was also attended with a peculiarly obstinate cutaneous eruption, which frequently extended into blotches and sores, from what circumstance I know not, but it obtained the popular name of merino itch This eruption often resisted the usual remedies for common cutaneous affection To effect a cure, it was often necessary to have recourse to active mercurials externally, and alternatives internally May not this disease have been a precursor of one of more violence that followed it—the winter epidemic?

"The method which proved most successful in the cure of these fevers was—in the intermittents, effectually to cleanse the alimentary canal, and in the intermission, to administer bark (cinchona) bitters, wine, etc., and during the febrile stage, diluents and sudorifics The patient was sometimes much benefitted, but anticipating the fit, by an anodyne, or an anodyne combined with sudorifics It was sometimes necessary to vary the mode, by anticipating the fit, with blisters, or substituting mineral preparations instead of, or combined with the bark

"We have remarked, that the fever was more mild in the autumn of 1811, than it had been during the preceding years It exerted less force in its action, and the cases were less numerous The disease declined early in the fall it seemed to have spent its force, and finally suspended its operation on the human system, not only for this year, but nearly so for every year since, so that it may be considered, that here terminated the train of summer and autumnal bilious disease, and our county has been subject to very little of that character of disorder since"

fusion,' in consequence of the prevalence of malignant disease (yellow fever), which appeared with threatening devastation—our county has in general this season enjoyed an unusual degree of health. The autumn brought with it some cases of remittent fever, attended more or less with bilious symptoms, which in some instances has showed a disposition to protect its existence to a very considerable length. Whether this is owing to some peculiarity of the season or the type of the disease, or to some other cause, remains for further observation to determine."

In closing the paper the author says "It will be perceived that the practice of medicine is not a business of nostrum or specific—that diseases are not to be met with, simply confined within the lines of nosological arrangement, nor cured by specific remedies for specific diseases, but that the character of the disease, the stage of the case, and the grade of excitement, ought to govern the prescriptions—that a faculty of discrimination in detecting and applying remedies to them, constitutes the most correct and most skilful physician. In such reflections, the members of this Society will see the importance of their situation. Organized under the patronage of an enlightened legislature, they become the guardians of the public health, and may be enabled to overawe empiricism and promote a rational and systematic method of managing diseases."

The second address of the book was given before the Dutchess County Medical Society at its annual meeting in November, 1825. It begins with a description of the diseases prevalent in 1820. Dr Sherrill says

"The year 1820 commenced under very favorable circumstances of exemption from general disease. A very few cases of phlegmasial affections marked the winter and vernal period. A few intermittents and mild remittents were the principal train of diseases of the first summer months. As the season advanced, the dysentery became epidemic in some sections of the country it was attended with obstinate and alarming symptoms, and in many instances with fatality. The various ordinary derangements incident to this disease of the alimentary canal took place, which was frequently attended with considerable arterial action and fever. Bloody discharges from the bowels was almost an invariable symptom. The evacuations were sometimes scanty, attended with tenesmus, but frequently they were copious, particularly after cathartics were used, and they frequently had the appearance of thick, bloody water."

The doctor describes his treatment as follows

"In the early stage, particularly as the cold season approached, bloodletting in some cases was beneficial. This was best to be succeeded by emetics of ipecacuanha, or cathartics, of which calomel was a leading article, with something to aid its operation, when it was very serviceable

to give remedies to determine to the skin, and sheathe the lining of the bowels. It was also found highly beneficial to give opiates occasionally, and particularly as an anodyne at night, in sufficient quantity to allay the pain and irritation. These remedies were to be followed by astringents, tonics, etc., as soon as the case would bear it. In several instances, as is perhaps too apt to be the case, time was lost by beginning with astringents too early, before the vascular excitement had been removed in the early stage. The fatal cases were about in proportion of one to twenty."

Concerning the diseases of the next year, the author says

"In 1821, nothing peculiar marked the early part of this year. In some sections of the county, phlegmasial diseases prevailed to a moderate degree, particularly those of a peripneumonic type. They generally yielded to antiphlogistic remedies. It was a peripneumonic attack of this kind in May that terminated the life of the first President of this Society, Dr Samuel Bard.

"Much is due to him for procuring the passage of the law by our Legislature, under the auspices of which we are this day assembled, and out of which has grown that advancing respectability of the medical character which, by the irradiating influence of science, has overawed, and almost obscured empiricism."

The author adds in a note "No one thing, perhaps, is better calculated to correct medical abuses and professional jealousies, than well regulated medical societies. To effect that object it is advisable to have judicious laws, and those regularly enforced."

Dr Sherrill describes smallpox in Dutchess County and its diminution "after the introduction of kinpox." In July, 1808, a case of smallpox occurred in the Alms House of New York City, and started an epidemic which spread to Dutchess County where it produced many deaths during the following winter. "Much of its influence was resisted by the use of kinpox. From the use of kinpox and probably in some measure from the subsiding or passing by of the atmospheric predisposition to produce smallpox, the disease disappeared in the spring of 1809."

The author says that very little was heard about the existence of smallpox until 1823, when numerous cases appeared in various parts of Dutchess County, most of which were varioloid. Dr Sherrill gives a lengthy discussion upholding the protective value of vaccination with kinpox.

Measles is briefly discussed, and a fatal pneumonic type of black measles is described.

Dr Sherrill also made general remarks about lung diseases, and says

"The disease, which is more general than any other among us—which terminates more lives than any or all others to which our community is subject—which prevails every year, and at every season of the year, but more generally in

"In the operation of the cathartics, there was generally a copious discharge of bilious, feculent matter. After the bleeding, the pulse commonly became more full and fair, which was particularly the case after the other evacuations, and then the patient was pretty readily got into an easy moisture, by diluting drinks and gentle sudorifics.

"The case occasionally so far partook of the phlegmasial type, as to require a repetition of the bleeding, and that sometimes on the sixth or seventh day, particularly in the latter part of the spring. In 1812, R. Nelson, Esq., now editor of the *Indiana Herald*, who was very much prostrated in the attack, was bled at first, after which, the symptoms were such as to require two more bleedings to remove the disease. The system appeared to be relieved, and reacted much better in many cases by taking a small quantity of blood at first, and repeating it. This was in imitation of the slow manner in which nature discharged the blood in those cases of spontaneous hemorrhage.

"In that type of the disease in which the lungs were not affected, blood-letting generally appeared unnecessary. The first remedy, therefore, was an emetic, or a course of cathartics. The purgative medicine was given so as to produce a number of copious evacuations; these were followed, intervened, or combined with diluents and sudorifics, and externally blisters, or some other application to parts locally affected. I was often agreeably disappointed, on making a second or third visit, to find the patient, particularly children, who had been considered dangerously ill, sitting up, or in a playful, or comfortable, or convalescent state, after the operation of the evacuating medicines. In this type of the disease, the remedies varied very little from those which had been successfully used in the bilious remittent fever of the preceding years, except an earlier and more liberal use of wine appeared servicable."

Dr Sherrill then gives some statistics of the cases which he saw during the second winter of the epidemic. The cases numbered 112 of whom 61 had lung involvements and were bled—five twice and one three times. There were seven deaths. Four of the fatal cases were of intemperate habits. "One had been in the habit of drinking from a pint to a quart of spirits a day, so said his friends. The disease seized him like a whirlwind, and soon carried him off. The other three intemperates having recently come into the place, had their prejudices about them, and obstinately refused being bled, though their situation urgently required it. One of them died in a state of furious delirium, with full symptoms of depression and turgescence of the system. One of the others took few or none of the medicines directed, and got little or no nursing. If those four that literally destroyed themselves are deducted, one hundred and eight cases remain, out of which

there were three deaths—equal to one in thirty-six."

The third outbreak of disease to be described was of an uncertain nature. The author describes its origin as follows:

"In the autumn of 1814, our citizens were affected, and in some instances fatally so, in consequence of a febrile disease, which appeared to have its origin with the militia who were doing camp duty at Harlem and Brooklyn, in the vicinity of the city of New York. From this circumstance the disease received the appellation of the Harlem or Brooklyn fever. There might have been some propriety for it as a common or popular name. Owing to a pretty large detachment of the militia of this county being sent there on military duty, a number sickened there, and some died, some sickened and came home on parole, and others sickened after their return.

"The disease, however, was not confined to this class of people, it occasionally attacked others, though the principal part of the cases were among those of the family or attendants of those who had been in the army.

"The symptoms attending the disease were rigors, pain in the head, back, and limbs, the stomach was more or less disordered, the eyes were red, or bloodshot, tongue slightly furred, pulse sometimes full and firm, and at others small or yielding."

The treatment was by blood letting, emetics, and cathartics.

The fourth epidemic was one of sore throat, which began early in the year 1819. The soreness was accompanied by membranes and external swellings, and sometimes with suppuration. That the disease was probably due to a streptococci infection is confirmed by the closing paragraph of the description.

"Mingled with this complaint, and immediately following it, we had cases of pneumonia, influenza, rheumatism, etc., in all which, as well as in all febrile diseases of the forepart of the year, there has been a peculiar disposition to affection of the head, with pain, stupor, and sometimes delirium. Those cases of catarrhal pneumonia and affection of the head, with fulness, stupor, and some delirium, came near proving fatal in several cases, they were cured by large bleedings, and other active evacuations."

The epidemic of sore throat was followed by an outbreak of "cyanchae maligna, or scarlet fever." The author continues, "No deaths occurred."

Referring to the events immediately preceding the meeting of the society, Dr Sherrill said "While the inhabitants of the metropolis, and the cities along the sea-board, almost from one end of the territory to the other, have been excited by fears and anxieties, and shunning the seats of pestilence, and fleeing their homes in 'wild con-

## PRENATAL CARE\*

By ASA B DAVIS, M.D., F A C S, NEW YORK, N Y

THE care of women during pregnancy is not entirely a new development. In the distant yesterdays there were private practitioners who devoted themselves largely to obstetric cases, with good results. They had no hospital facilities, no laboratories—except a few essential reagents and microscopes in their offices. These they used, not in the systematic routine which is followed in our time, but as indications then pointed to their need. It was necessary for them to be close clinical observers. They were the trusted family doctors and friends, almost members of the families which they watched over. They possessed a training and aptness for their work, guiding the majority of their patients safely through the process of reproduction, even though their repair work was woefully inadequate. They were outstanding men in advance of their times. Were they with us today they would use the knowledge and facilities which we possess, and which too many of us do not employ, and they would still be in the van in obstetric practise. We have such men, better trained, in every way better equipped, who are quietly doing creditable work in caring for obstetrical patients in their homes. There are not enough such obstetricians.

I believe it will be instructive to go back forty years and glance at the hospital facilities for maternity cases in this city. There was the Lying-In Asylum, since merged in the Nursery and Childs Hospital; Bellevue had about a dozen beds for emergency cases, the Charity Hospital on Blackwells Island had rather an active obstetrical service, Nursery and Childs Hospital, Infant Asylum, Foundling Hospital, the Brooklyn City Hospital, Long Island College Hospital and Kings County Hospital, in all, probably two hundred and fifty beds is a generous estimate.

Some of the general hospitals would occasionally admit maternity cases and care for them in the wards with other patients. In 1888, Sloane Maternity was opened and hailed as a step in advance. While it took high rank with the institutions of that time, and is among the best of today in practise, teaching and results, the early best, according to present standards, was not very good. Like the other maternities of that date, it had its share of sepsis, eclampsia, hemorrhage, morbidity and mortality. Prenatal care, as then known and practised, would be accorded too much dignity by even calling it a gesture.

Formerly, our immigrant population was of different stock, coming largely from the agricultural classes of northern Europe. They were more developed, intelligent, had lived better and presented fewer problems than those who

swarmed in from southern Europe and the near east forty or more years ago. Many of these settled in the lower east side of New York, adding to the squalor already there, and presenting such examples of crowding, ignorance, filth in person and surroundings as would be difficult to find anywhere now. The midwife flourished. Not the type who had received long and careful training in the maternities of Europe, but usually the ignorant woman of middle age, who had reared her family, and without training taken up the duties of accoucheur, cook and housekeeper in the families which she attended.

In 1890 a group of men organized the Midwifery Dispensary which was merged three years later in The Society of the Lying-In Hospital of the City of New York, giving life and activity to this ancient organization which had been quiescent for many years. They began work in the tenements of the lower east side with headquarters in Broome Street, patterning their work at first after the out-door department of the Boston Lying-In Hospital. It was my good fortune to be called as lieutenant to this group of men, a few months after the organization of the Midwifery Dispensary, to act in the capacity of resident physician. The chief motive which actuated them was the training of undergraduate pupils in obstetric practise. The records show that during the first year 199 women were confined, in the second 955.

Upon looking back, it seems to me rather remarkable that these men possessed a vision which should materialize in later years into something like "prenatal care" as we understand it today.

For instance, at the beginning of the second year, and thereafter, a new form of history chart was employed which called for a detailed obstetrical history of the patient. Physical examination was made, and careful external and internal pelvimetry, height and weight were taken. The expression of the countenance, now too often written "cheerful" or otherwise, was noted, the idea being to quickly detect or call attention to the facies of possible tuberculosis, cardio-nephritis, rickets. Attention was paid to the attitude of the patient, searching for any readily apparent skeletal deformities, spinal curvatures, hip diseases and so forth. The breasts were inspected for changes due to pregnancy, deformities of the nipples, and as to the prospects of the mother being able to nurse her child. Measurements were taken of the height of the fundus uteri, and urinalysis done. Another chart called for notation of the salient points of labor in considerable detail, also the condition of the child, sex, weight, total and vertex coccygeal length, various circumferences and diameters. There

\* Read at the Annual Meeting of the Medical Society of the State of New York at New York, March 30, 1926

cold weather—is the different grades of inflammation of the chest, arranged by nosologists under the various terms of bronchitis, influenza, peripneumonia, pleurisy, pneumonula, etc

"It has been three times epidemic within our time In 1807 the influenza with peripneumonia spread through the county and extended itself over the United States It was so universal in its operation that all, or nearly all, felt its influence The late Dr Wheeler of Red Hook observed that he did not know a person in that town who had escaped it

"The disease that prevailed last spring was of a very active phlegmasial type As is observed by John Bell, 'the lungs were frequently stuffed and crammed with blood' When exhibiting a small pulse, prostration of strength, and a pallid countenance, there was the most urgent call for bleeding And I have not met with a disease where the patient required more bleeding, or in which he bore it better Although some cases recovered without the use of the lancet, yet in most cases of much activity it was used with advantage, and frequently it was necessary to be several times repeated"

Dr Sherrill seems to put much stress on a classification of diseases into two types, the inflammatory and the typhoid For the inflammatory diseases, blood-letting, cathartics, and sweatings were prescribed in order to "deplete" the system and remove congestion For the typhoid group, tonics and stimulants were used The book contains much discussion regarding these two types of diseases Dr Sherrill says

"It has been considered that in many instances this disease is connected with a typhoid diathesis, or that there is a great proneness to that state of the system Hence we hear of pneumonia typhoides, of typhus supervening, and that the patient may be run down if depletion is used, etc As far as my observation has extended, I have not observed such a state

"In addition to the testimony of a number of my medical brethren in favor of the asthenic nature of those diseases, their inflammatory character will appear, when it is observed that the antiphlogistic depletory course of treatment was uniformly pursued, and that out of the numerous cases that passed under my prescription, there was but one death (a child), and one case which terminated in consumption The patient has since died There was no case that exhibited a black tongue, or in which a typhoid state supervened

"Whatever the diathesis of disease may be, as we leave the banks of the Hudson and approach the Connecticut River, I have not been able fully to determine But, as it relates to our county, it will prove a dangerous delusion to adopt the position of Dr Miner, that the inflam-

matory nature of disease has entirely left our country, and that 'all diseases partake of a typhoid character' Numerous facts are not wanting to show the generally decided inflammatory or congestive nature of our diseases"

Childbed fever is the last disease discussed in the second chapter of the book Dr Sherrill considered it an inflammatory disease to be treated by cathartics and bleeding He acknowledges the inefficacy of all forms of treatment, and says

"It ought not to detract from the reputation of a practitioner to lose his patient in this disease, after the avowal of such men as Burns, that he could say what had failed, rather than what had cured, of Bard, who declared it to be a most fatal disorder, of William Hunter, who used bleeding and cathartics in one woman, and she died—sudorifics and fomentations in another, and she died, who tried the stimulant plan in another, and she died, in short, all plans failed, or of a Professor in Edinburgh, who, as we are informed, lately told his class that he considered it an incurable disease."

The book also contains an article on "Canes of the Jaws of Children," which was given before the Medico-Chirurgical Society of the University of New York in 1808, while Dr Sherrill was physician to the Alms House The disease seems to have been an aggravated form of advanced scurvy, possibly complicated with Vincent's angina Dr Sherrill says

"In the inquiry into the causes of this affection, it will be proper to take into consideration the situation and diet of those who are subject to it In an institution like the Alms House, there is necessarily a numerous collection of persons in one room In the nurseries appropriated solely for children, there are about fifty or sixty inhabiting the same apartment, who consequently sleep, eat, and respire within a small compass Medical history informs us, that the diseases of confined and crowded places have a gangrenous tendency, and experience confirms the remark. Though particular attention is paid to cleanliness in those rooms, there is more or less miasma generated and floating in the confined atmospheres, which will assist other causes in producing diseases, or render diseases obstinate which are otherwise produced

"Their food is principally brown bread and molasses, though sometimes they have white bread, and latterly, considerable sugar instead of molasses"

As to treatment, the author prescribes mouth washes, tonics and Peruvian bark It is interesting that the solution of copper sulphate which he found of value is still a standard form of treating Vincent's angina

urine and blood pressure timely observations have been made, it is extremely rare. During six months in 171 emergency labors, one in every eighty-five had eclampsia, while in 2,515 regular applicants in the same period who had more or less prenatal care, eclampsia occurred in only one of four hundred and twenty cases. The latter all gave warning signs of a developing toxemia. We can by no means always prevent eclampsia, but we usually can anticipate its occurrence." Adding to these statistics up to December 31, 1925, we find that for the whole year of 1924 there were thirteen cases of eclampsia, four being emergencies, and during 1925, eleven, three of which were emergencies. Similar experiences are being reported from maternities throughout the country where prenatal care is carried out. The results achieved in gaining better control of this one complication of pregnancy well repays all efforts expended in prenatal care.

It would be difficult to summarize all of the other good results. Patients apply earlier in their pregnancy and keep themselves in better condition. There are fewer cases of threatened abortion and, where this threat does appear, more are successfully treated and carried on to full term. The cases of pyelitis are detected earlier, cardiacs are supervised with more satisfactory results, pelvic deformities and disproportion between the pelvic capacity and the unborn child are foreseen, there are fewer premature births, and thus we could go on throughout the entire list of abnormalities which may occur during pregnancy.

I think the reports of several cases are instructive. About two years ago, two multiparae were admitted to the wards of the Lying-In Hospital on the same day. One had applied previously, been examined and instructed to return at regular intervals. This she failed to do and was lost trace of, being brought in about four months later in labor, a well developed eclamptic. The second patient was seen for the first time by a physician in the suburbs who recognized her condition by blood pressure and urinalysis. Within a few hours she also was admitted to the hospital, soon developing convulsions. Both of these women were delivered. In each case there was suppression of urine, all symptoms became worse and, failing to respond to treatment, died within a few hours of each other, thirty-six hours after admission to hospital. They had both been delivered of several children without trouble. Doubtless, pressure of work and the care of their families, and the fact that they had safely passed through previous confinements, made them neglectful of their condition. One, contrary to advice, the other having had no supervision whatsoever. In each case, a family of young children was left, the mothers dying unnecessarily.

Several months ago a primipara nearly at full

term was brought to the hospital in an ambulance, having repeated convulsions and showing all the well marked symptoms of toxemia. She had received prenatal care regularly from early pregnancy, having visited the hospital ten days before when observations were made without revealing any untoward symptoms. She recovered, but the child was stillborn, due, so it was supposed, to intoxication. A private case, a primipara pregnant with twins, under regular observation showing discomfort and moderate oedema. On February 2, blood pressure was 110, and there were faint traces of albumin in the urine. This has been present throughout pregnancy and was probably due to vaginal contamination. On February 16, blood pressure was 134. There was marked swelling and pain in the lower right extremity, also some headache. Urine report received on the 17th showed the presence of a large amount of albumin, hyaline and granular casts and considerable pus. This patient lived out of town but appeared at the hospital in response to a call about four hours after the report had been received. Blood pressure at that time was 150, and urinalysis similar to that already mentioned. Although two weeks from calculated full term, her abdomen was so large and tense, and the symptoms so sudden and alarming that induction of labor was begun shortly after her admission. Eleven hours later there was evidence of fetal distress, uterine contractions were forcible and frequent, cervix dilated to about 4 cm, and blood pressure 165, there was headache and occasional flashes before the eyes. Delivery was by lateral incisions of the cervix. The first child was delivered by medium forceps, and some of the delay in dilatation accounted for by posterior position and a very short cord. The second delivery was by version. Each child weighed between five and six pounds and was living. The cervix was repaired and in a few days all untoward symptoms disappeared. It is fair to say in this case that great added nervous strain was placed upon the patient owing to the serious illness of her husband. However, it seems to me that these histories point to the advisability of observation being made at least once a week during the last month of pregnancy. In this case eclampsia was undoubtedly averted.

Over a period of twenty-five years or more there has been a progressively increasing interest in and provision for obstetric cases. This is not limited to any locality but is general through the whole country. The bed capacity for maternity patients has been expanded by many thousands, and attention focussed upon this branch of medicine which is being studied not only by those in charge of maternity services, but by medical and lay, public and semi-public organizations. Thus we find in 1921 the American Association of

were places to record the condition of the placenta, cord and membranes, any deformities or injury to the child and the condition of its circulation and respiration. There were still other headings calling for notations in regular order of the subsequent condition of mother and child. With few changes, this form of chart is in use at the present time. It was a comparatively easy matter to work out such charts on paper, but it was quite a different thing at first to induce prospective patients to submit to the examination called for. We were dealing with ignorant, apprehensive and easily frightened people who had been accustomed to treatment by midwives, or by doctors who had little or no time for, or belief in the necessity of observation during pregnancy, and were called in to attend the delivery and perhaps make a few calls thereafter.

There was great poverty in the lower east side, and our first patients were those who came because obstetric care was furnished free of any charge. At first it was slow and uphill work to induce these women to become patients and submit to any kind of examination, many of the earlier cases were not examined very thoroughly. Often, when placed upon the examining table they would make a great outcry, thereby stampeding a dozen or more waiting patients. Gradually this state of affairs was overcome, the work grew rapidly and was limited only by the ability of our staff to care for these cases. One August we confined 357 women in their homes. As a rule these women made application during the last weeks of their pregnancy. An attempt was made to secure subsequent urinalysis by providing each applicant with a bottle, labeled with directions, to be returned at a given date. This was almost entirely unsuccessful. I mention these conditions to contrast them with our experience at present.

Now, our patients come gladly, and readily subject themselves to what must be a somewhat irksome series of questions by the history clerk, social worker, and, for the in-door patients, the financial clerk. They willingly allow examination without complaint, apply earlier in their pregnancy, and nearly all return at stated intervals as directed for observation, instruction, urinalysis and blood pressure. From 2 to 3 per cent of the applicants show positive Wassermann. These receive systematic care from a specialist in the hospital.

Our patients seem eager to co-operate and learn everything possible that will aid them in doing their part to take proper care of themselves during pregnancy. These results have been attained only by gradual education of the people seeking free or nearly free hospital care. Like instruction is going on in similar institutions. These women would not submit to the expenditure of time and necessary inconvenience had they

not learned to believe that by so doing they were securing something of great value.

Up to eight or ten years ago, as we had long believed and have since tested, something was lacking in the care of our pregnant women. Early in our history, in the case of patients whose examinations showed deformed pelvis, cardiac disease, nephritis, the presence of new growths and so forth, an abnormality chart was affixed to the usual chart of pregnancy. This was well as far as it went, but the follow up of such cases was not systematic, and too often the value of these observations was lost on this account. In all branches of medicine it had long been felt that hospital and dispensary patients especially suffered a great loss by the failure to follow up and advise them until they were restored to health, and that doctors, in their turn, were deprived of much valuable knowledge because in too many instances they were unable to know the end results. While this need had been recognized and discussed for several years, the appearance of a remedy in practical working was comparatively sudden all over the country. Some institutions were able at once to establish a complete social service and follow up system to account for every patient and, from time to time, such patient's condition. The great benefit derived from this course was at once apparent. The better maternities throughout our country have achieved almost startling results by adopting this plan, designated as "ante-partum" or "prenatal" care, and it is safe to say that in the last six years the appearance of convulsive toxemia in such institutions has been reduced by at least 75 per cent. Other complications of pregnancy have, in many instances, been detected in their incipency and corrected before they became serious. This, I take it, is good preventive medicine.

In this connection I think it is illuminating to quote from an article written by Dr. James A. Harrar, of the Staff of the Lying-In Hospital. Dr. Harrar says: "The incidence of recognized severe toxemia as expressed in cases admitted to the wards for treatment has increased. In 1919 there were nine, in 1920, eleven, in 1921, twenty-eight; in 1922, forty-two, in 1923, thirty-one, and in the first six months of 1924, twenty-eight. While we have been discovering and recognizing more toxemia, we find to our great satisfaction the incidence of the convulsive type, eclampsia, has extraordinarily decreased. Formerly we would have forty and fifty cases every year, but in 1919 we had twenty-seven cases, in 1920, twenty-three, in 1921, twenty-two, in 1922, eight, in 1923, thirteen, and in the first nine months of 1924, nine. Perhaps an eclamptic convulsion can develop without warning, but in a pregnant woman whose careful prenatal instruction has taught her proper living and on whose

the records are conveniently at hand. Like results can undoubtedly be found in the reports from some other hospitals.

#### WOMAN'S HOSPITAL

1923—Confinements	1103

The nurse who carries through instruction and advice in informal talks with pregnant women is a very important factor in prenatal care. There is a rapidly growing public which

receives prenatal observation and guidance. There must still be a vast public which is indifferent, ignorant and careless. Nor is this limited to the lay public. There is far too large a contingent of the medical profession which come under this heading.

The excuse is often made that the bad obstetric results are chargeable to the rural districts. In part this may be true, but it is the whole truth. No worse results can be found than those often witnessed in cities. In the maternities showing the best results, there is still room for improvement. At least, they have shown the way in which progress is being made. The lack of hospital facilities is given as another explanation by the private practitioner. This excuse is not valid. Any procedure in obstetrics, even Cesarean section, can be successfully conducted in the patient's home. Complications are more conveniently managed, observed and nursed in a well equipped hospital. Out-patient departments care for thousands of women in their clinics and deliver them in their homes. Much of this work is actually done under supervision, by doctors and pupils whose training is not far advanced, for patients and in surroundings quite as unfavorable as any to be found in private practice. The results differ very little for the various institutions and are surprisingly good. In morbidity and mortality they rival those of the indoor departments.

Several years ago, during four and a half consecutive years, in the Out-door Department of the Lying-In Hospital, between ten and eleven thousand women were confined in their homes without one maternal death. Of the complicated cases sent into the hospital during this time, twenty died. A maternal mortality of five-tenths of one per cent.

Great responsibility rests with the obstetrician. This cannot be delegated to nurses or lay organizations. It is very important to secure a thorough history of the pregnant woman. The primipara is, obstetrically, an unknown quantity. But a reasonable forecast of the outcome of her confinement can be arrived at by careful observation and examination. It should not be possible in this day and age for a woman to continue having stillbirth after stillbirth, or terribly injured children, because of disproportion between pelvis and fetus. Pregnancy continues over many months. During that time more of the gross complications which will appear at confinement, than is now the case, should be foreseen and provided for in advance. More doctors who practice obstetrics need to take honest account of themselves and recognize their inadequate equipment in obstetrics, learn to keep their hands off complicated cases to the end that fewer of these are admitted in labor, or in-

Obstetricians, Gynecologists and Abdominal Surgeons, at their annual meeting, appoint a committee on maternal welfare which has since been working in conjunction with a like committee appointed by the American Gynecological Society. The reports of this committee give evidence of intensive study and far-reaching work. The scope of this paper does not permit more than brief excerpts from these reports. In one place we read "Due to long and active efforts at prevention, Birmingham (England) has the lowest rate of morbidity and mortality of any large city in the world. That city, according to the *Bulletin*, Department of Health, New York City, May, 1921, during the years 1915 to 1921, shows a death rate from puerperal causes averaging 31.94 per 10,000." Further on we note "The State of New York, 1915 to 1921, inclusive, shows a death rate from all puerperal causes averaging 54.9. In New York City the rate was 46.1. Puerperal septicemia mortality in New York City for the period was 30 per cent of the total mortality. Maternal mortality from all causes varies but little in New York State, while there was an increase in 1918, due, doubtless, to the prevalence of influenza, the average for the five years was 14.4. In puerperal sepsis in 1919 New York City showed the world's low record of 11.4 per 10,000." And also the following: "The report of Dr Alfred C Beck of Brooklyn, in a paper entitled 'End Results of Prenatal Care,' gives a table of comparisons of three series of 1,000 cases each, with the following results:

- Series 1 No prenatal care—stillbirths, 35, infant deaths, 41, total, 77
- Series 2 Visiting nurse, but no physician—stillbirths, 25, infant deaths, 22, total, 47
- Series 3 Prenatal care throughout, under medical supervision—stillbirths, 19, infant deaths, 6, total, 25"

These statements deal briefly with the conditions in New York City and State. Reports are made from many other states and large cities. The whole report of this committee is worthy of most careful study. Birmingham, England, is a large manufacturing town. It undoubtedly has slums as well as all other grades in the social and economic scale, yet, according to the report, it maintained its enviable record over a period of six consecutive years. I cannot believe that the results obtained were brought about by one group, but were arrived at by concerted effort and co-operation of doctors, nursing organizations, maternal and health centers, and a guided and instructed public. While we cheerfully give all allowable credit due to prenatal care, and it is much, we cannot ascribe the great achievements in obstetrics in recent years wholly to this phase of the work. If New York City has shown the report of maternal mortality as stated above for

1919, I am confident that this is far beyond its irriduceable minimum. The results can be made far better than this report shows.

In maternities where prenatal care is the rule, bed capacity is taken up for months in advance and in this way the possibility of admitting many emergency cases is reduced. Better results is the experience in such institutions until those who are responsible for these results feel a possibly not-too-well-founded assurance that obstetric practice as a whole has improved. While to some extent this is true, such confidence is too often rudely shaken. Thus, at the present time there is a patient in the wards of the Lying-In Hospital, slowly recovering. She was admitted as a emergency case giving a history of several days' labor, unsuccessful attempts at high forceps and craniotomy, showing a mutilated and infected vagina and cervix, third-degree lacerations of the perineum, a vesicovaginal fistula, and an undelivered, mutilated, dead fetus.

One needs but to enquire at the maternities of our city hospitals where emergency obstetrical cases in considerable numbers and many in desperate condition must be admitted, or to do consultation work in obstetrics, to be impressed with the amount of dreadful work, and the woeful lack of care thus made evident here in our city today.

Several months ago a committee on public health and hygiene met in New York and issued a brief report in the public press, which stated "Although great progress has been made in the care of maternity cases in some areas, there has been no improvement in obstetric results, in the country as a whole, during the past twenty-five years." The committee on Maternal Welfare of the American Association of Obstetricians, Gynecologist and Abdominal Surgeons states that annually in this country sixteen thousand women die in the process of childbirth. J S Herbert, M.D., of New Orleans, presents a paper in the present March number of the *American Journal of Obstetrics and Gynecology* "A Critical Analysis of 250 Prenatal Charts." This paper should be carefully studied. Dr Herbert states "Conservatively estimated, 25,000 women die every year in this country from immediate or remote effects of childbirth. Approximately 8,000 from infection, 5,000 from eclampsia and 4,000 from hemorrhage. And all these deaths, if not preventable entirely, are at least capable of being greatly reduced."

In obstetric records in eighteen nations studied, the United States, as a whole, ranks among the lowest. While this is undoubtedly true, yet there are maternities in this and other cities of our country which achieve unequalled results. It is probable that in the future these results will be surpassed. A few statistics are instructive. These particular hospitals are selected because

ing as a rule in early life, the attacks usually cease or change in character spontaneously at the climacteric. They come with varying periodicity, are of short duration, with intervals of ordinary well being between the attacks. With the headache there is usually associated nausea and vomiting and at times visual and vague somatic disorders, and lastly its recurrence is independent of those accidental causes which determine other kinds of headache.

It is now beyond doubt that migraine is in a very large majority of cases an hereditary malady. It is rather unusual on close questioning to find a patient suffering from migraine who does not give a familial history. Buchanan, after a statistical study of hereditary migraine at the Mayo Clinic, claims that the heredity follows the Mendelian law of inheritance. His work is extremely interesting and if verified would lead to many important conclusions. For example, the migraine tendency would have to be considered as an innate constitutional characteristic as deeply set and as ineradicable as the color of the hair, or tallness or any other inherited feature.

The location of a headache is important from a diagnostic viewpoint, but there is no rule of thumb for determining the cause of a particular headache by the position. All unilateral headaches are not migraine and all migraine headaches are not unilateral. Headaches resulting from a one-sided sinusitis give beautiful pictures of hemicrania. So also does glaucoma. The so-called rheumatic or neuralgic headaches and the indurative headaches are usually one-sided. On the other hand, migraine headaches are frequently bilateral or alternating or deeply centrally located. As a matter of fact, the pain of migraine is usually so intense that the patient finds difficulty in localizing it.

The nausea and vomiting, which frequently accompany an attack are usually so outstanding that the rest of the symptom complex is often overlooked by the physician. He attributes the attack to some digestive disorder. Many a case of migraine is buried under the vague blanket diagnosis of biliousness. Beyond the fact that bile-stained mucus is brought up after prolonged wrenching there is nothing but a hypothetical disorder of the liver. It is true that chronic cholecystitis is at times met in association with migraine, and this may act as an exciting factor in producing attacks, but it cannot be the fundamental basis of the malady. We believe that this vomiting, coming at the peak or climax of the paroxysm, is cerebral or reflex in origin because in the usual migraine case there is no consistently demonstrable gastro-intestinal disorder, functional or organic.

The visual disorder in migraine has always attracted particular attention. Its main characteristic is a blind area usually to one side of the centre

of vision, coming as a rule at the onset of an attack. These are usually described as scintillating, or like a redoubt or fortification. They are of short duration, in the typical case lasting from fifteen to thirty minutes. Many explanations have been offered, the most widely accepted being that the disorder is due to a disturbance of the cerebral circulation of the visual area. Our belief, however, is that these visual symptoms are caused by pressure of the physiologically enlarged pituitary on the optic chiasm.

But perhaps the most important ear mark of migraine is its periodicity, extending over the greater part of the patient's life, the attacks as a rule being unassociated with the ordinary causes of headache, such as constipation, eyestrain, etc.

Just as important as the recognition of the typical migraine outlined above is the recognition of the migrainous tendency in its various atypical and abortive forms. It is rather common to see patients who have periodic attacks of scintillating scotomas without the development of headache. Also there are cases where headache alone or vomiting alone or mental confusion and aphasia alone constitute an attack. The makeup of the individual, his family history, together with occasional complete attacks give a key to the diagnosis.

Abdominal migraine has been described but the diagnosis is of doubtful standing. Epilepsy and glaucoma are from time to time considered as late developments of migraine, but discussion of this point is beyond the scope of this paper.

A review of the literature on migraine reveals a multiplicity of alleged causes for the malady. There is hardly a human disorder that has not by some one or other been suspected of being the basis for migraine. In late years there is a tendency for each specialty to claim migraine for its very own. The eye men claim that it is due to refractive errors, the nose and throat specialists that it is due to infected tonsils and sinuses, deflected septums and irritated sphenopalatine ganglions. Constipation is a convenient category to which to assign these patients, as well as chronic cholecystitis. Various pelvic disorders, ovarian, uterine, and menstrual are blamed. Protein fat, and carbohydrate has each been blamed. Excess uric acid, a deficiency in calcium, nitrogen retention, and hyperbilirubinaemia are mentioned. Focal infection is, of course, mentioned as a cause for this as for many other diseases.

None of these explain migraine. It is unreasonable to claim that an abscessed tooth or a cholecystitis, or any other recently developed pathology, is causing a migraine which has had its inception in early childhood and continues to the climacteric. The very nature of the malady stamps it as deep set constitutional disorder.

Constipation or eyestrain or a retroverted uterus may be the immediate exciting cause of a particular migrainous attack, but this is not the fundamental explanation. For example, a patient with

fectured by careless unclean examinations, or with mother and fetus mutilated by unsuccessful attempts at operative delivery made by those whose training in no way entitles them to the assurance which they manifest in undertaking such operations, too often after several days of labor. Large order as it is, I can conceive of no one thing which will do more towards better results in obstetrics than the doing away with the "emergency" case. Seeing to it that every pregnant woman in our land is given adequate prenatal care. It will take years for the forces now interested to accomplish this. In the meantime thousands of women are dying unnecessarily. So long as these deaths are numbered by thousands each year, it matters not whether it be fifteen or twenty-five thousand. We accept this state of affairs with complaisance, as we would not were the lives of these women suddenly wiped out in some small area. We need rousing, awakening to a vivid realization of this largely

avertable catastrophe which is now, today, taking place. The responsibility rests with doctors, various organizations, with each individual of the community, with all of our people.

### PRESENT DAY ASPECTS OF MIGRAINE\*

By EDWARD F. HARTUNG, M.D., New York, N. Y.

**H**HEADACHE is a symptom associated with such a great variety of disturbances that the diagnosis of the underlying cause in a particular case leads one practically through the entire field of pathological states. In any attempted classification of the different types of headaches the symptomatic headache must be eliminated in order to bring some order into the complex problem. In the group of headaches which are not merely transient and symptomatic there are those which are due to a definite traceable pathology such as meningitis, tumors, hydrocephalus, arterio sclerosis, etc. Of the group of headaches in which no definite pathology has yet been generally accepted, migraine easily demands our first attention. It stands out because of its peculiar and baffling nature, and the importance of its being recognized not only in the typical cases but even more so in the abortive and atypical cases.

For a number of years the problem of headache has been made the subject of study in the medical department of the Post Graduate School in New York. Lately I have had the opportunity in collaboration with Dr Ludwig Kast at the hospital and in private practice to study a series of patients whose main and outstanding complaint was headache.

Diagnostic classification of these patients runs as follows

Diagnosis	Number of Cases
Migraine	50
Nose and Throat Conditions	22
Eye	7
Ear	3
Respiratory Conditions	4
Gastro-intestinal	32
Gynecological	35
Neurological	16
Hypertension	12
Rheumatic	18
Miscellaneous	10
Undiagnosed	43

In this series migraine constitutes about 20% of the total number. Let me emphasize again that this series includes only patients whose outstanding and usually only complaint was headache. I think this accounts for the small number of cases due to eye strain, constipation and some of the other common causes, for in these cases the patients frequently make their own diagnosis and seek relief directly at other than the medical department for the causative factor.

First, I wish to review briefly the distinguishing features of this type of headache, especially for the reason that by some it is felt that migraine is not a distinct clinical entity at all. However, after a careful study of headache patients, it seems to us that the clinical picture of migraine stands out as clear cut as most recognized diseases.

Briefly, migraine is an hereditary malady characterized by recurrent severe headaches. Begin-

\* Presented before the Buffalo Academy of Medicine by invitation on October 27, 1926.

outstanding pathology should be removed, but the necessity for operation should be weighed with great care. Intestinal hygiene should be the first line of attack. The treatment of constipation will not cure the patient but will contribute to make the attacks less frequent. Emphatically I do not think there is any special diet for migraine. The diet to be recommended should depend on the abnormal states, if any found, such as intestinal putrefaction, fermentation, or cholecystitis.

The next line of attack should be directed against focal infection. Abscessed teeth, diseased tonsils, pus in the urine, etc., are definite contributory factors in migraine. Also correction of gynecological abnormalities is of extreme importance.

All this, of course, may be suggested for almost any medical condition, but a vigorous approach is especially important in migraine, because one is working in the dark, as it were, hoping that one may hit upon the irritating factors.

An extremely important duty is to impress upon the patient the realization of his low fatigue threshold, and this applies not so much to fatigue due to laborious work or exercise as to work associated with mental and emotional stress.

As to the drugs and medicines recommended for migraine, most will be found wanting. The list would include luminal, bromide, cannabis indica, caffeine, strychnine, pilocarpine, ergot, atropine, nitroglycerine, calcium preparations for oral and hypodermic use, peptone injections, horse serum, placental extracts, and many others.

Endocrine therapy, however, gives some remarkable results at times. One is lead by the predominating endocrine disorder, if any, found. In accordance with our theory of the pituitary roll in migraine, we gave pituitary gland products a thorough trial, and recommend that you use them as an adjunct to your general treatment. One may give the pituitary hypodermatically, or by oral administration. In the former case we give  $\frac{1}{2}$  to 1 c.c. of anterior lobe extract, together with half that amount of posterior lobe extract. For oral administration, which is just as efficacious, in some cases, we give  $\frac{1}{20}$ th of a grain of the whole dried gland three times a day.

Small doses are advisable because they can gradually be increased, and large doses make the attacks more frequent. One may well be sceptical in believing that such a small dose as  $\frac{1}{20}$  of a grain has any physiological rôle whatever. But we feel that it has a decided effect on the organism. An interesting effect, not especially desired, which we have observed is that immediately on beginning the administration the bowels are somewhat loose. This effect lasts two or three days and then disappears. It is not noted in every instance but it has been such a decidedly recurrent observation that we cannot consider it a mere coincidence. Of course, in our cases where pituitary was tried, no other therapeutic measure or advice was given. Some patients received no benefit whatever from pituitary administration, but in most cases there was marked improvement with less frequency and less severity of the attacks. We have four patients who have had no attacks after the commencement of pituitary therapy. We continued the treatment for six months and they now have had almost three years of relief. In brief while pituitary is not at all a cure for migraine it usually ameliorates the situation.

Now it is to be remembered that a hypofunction of the hypothysis may be accelerated by stimulation of other endocrine glands which are known to be definitely linked to it, notably the thyroid, adrenals, and the gonads. Remarkable benefit in migraine is at times obtained by administration of thyroid or ovarian substance or corpus luteum, if the history and constitution of the patient indicates their need.

In conclusion permit us to say that this paper does not pretend to relate anything newer or more startling than a viewpoint. The age-old problem of migraine is still unsolved, but we feel we are gradually groping our way to an understanding of this interesting disorder. Its final solution awaits a further elucidation of endocrine and autonomic mechanisms. But at present let us at least recognize the condition when we are confronted with it, not only in its typical manifestation but—of even more importance, in its various atypical forms.

## A PLEA FOR BETTER REPORTING TUBERCULOSIS CASES

By ROBERT E. PLUNKETT, M.D.,

Director, Division of Tuberculosis, New York State Department of Health, Albany, N. Y.

**A** STUDY of the completeness of reporting cases of tuberculosis in this State, and a comparative study of our reporting, with records of other states, shows that there is much to be done if New York State is to assume the coveted first place among all of the states, in this phase of public health work.

During 1924, New York State stood fifth

among the states in the number of reported cases per one death in that year. If we adopt three reported cases per death in a given time as an accepted minimum ratio, there were only two states in the Union which had reached that goal, namely, Kansas, which had 33 cases, and Maryland, 3. Next was Illinois, 27, Minnesota, 26; Hawaiian Islands, 24, and New York, 21.

migraine may have an attack due to constipation at one time, emotional stress at another, or carbohydrate excess at another time. In short, removing the immediate exciting cause will almost never entirely effect a cure. The medical histories of some of these patients are pitiable indeed. Frequently they have run the gamut of medical and surgical specialists, they are wearing glasses, have had two or three nasal operations, have borne with great patience all kinds of diets, possibly have had their appendicities and gall-bladders removed, and yet they still have their headaches.

As to the theories of migraine which seek a more fundamental explanation must have merely an historical interest. Only two need our attention now. One is that migraine is a manifestation of a vasomotor disorder of the cerebral circulation, either transitory hyperemia or anemia or both alternating.

The other theory to which we ourselves are inclined is that migraine is a pituitary disorder, and proof is gradually accumulating to place this idea on firmer ground. Due to extra demand on the organism, the pituitary is called upon for an increased output of its secretion and with the acceleration of its activity becomes engorged and enlarges. Being inclosed in an inexpandible bony cavity, the sella tursica, its enlargement causes pain. The outlet to the sella is superiorly and here the optic chiasm is situated. De Schweinitz, in a recent monograph has shown that the chiasm is frequently in direct relation with the superior surface of the pituitary gland. Pressure on the chiasm could anatomically account for the visual symptoms, the scotomas, and hemianopias so often seen with migraine.

Many elements of the migraine constitution readily suggest an endocrine association, for example, the onset of the malady around puberty, and its cessation around the climacteric. Also the fact that women, while they may have an attack at any time, frequently have one around the menstrual period. Another interesting observation is that women who become pregnant are very apt to be practically free from attacks for the entire nine months, and after parturition the attacks will recur. This is not an invariable observation, but is common enough to be distinctly significant. Many factors in the symptom complex and the makeup of the patient suggest a pituitary disfunction. Such, for example, are the sympathetic nervous suppression or atonia exhibited by the low blood pressure that these patients usually present, the general asthenia, low fatigue threshold, extreme reaction from loss of sleep, and susceptibility to carbohydrate excess. During the attack there is apt to be slight diarrhea, irritable bladder, a still lower blood pressure, a slow pulse and pallor. All these suggest a vegetative nervous disorder, a suppression of the sympathetic tone, and more fundamentally suggest to us a dispituitarism with hypo-pituitarism pre-

dominating. It is to be recalled that the hypophysis, in association with the thyroid and the suprarenals, stimulates the sympathetics, a suppression of its activity leading to vagotonia. An attack of migraine would be considered an attempt on the part of the hypophysis to assist the control of sympathetic system when it becomes too attenuated.

We have X-rayed a large series of sella tursicas in these cases. The X-ray technique of taking the sella is variable, the apparent size of the sella being dependant almost entirely on slight variations of focal distances and angles. Besides no mathematical method of comparing the size of sellas as they present themselves in X-rays has been worked out. However, it is our distinct impression that the sellas in migraine patients are predominantly small, giving little room for expansion except upward. When an extra demand is made on the pituitary for an increased output of its secretion it has little room for expansion in a small sella.

It is true that while pregnant women are apt to be free from attacks of migraine, their pituitaries are definitely larger in size and weight. But this enlargement is a slow process in pregnancy and may not give symptoms, just as slow-growing cerebral tumors frequently do not cause disorders until decidedly large.

As to other laboratory observations in migraine one finds the patient peculiarly normal, considering the severity of his attacks. For centuries there has been in the minds of medical men a vague association between uric acid and migraine. Our series fail to show it. We were also interested in the blood calcium, sodium and potassium in migraine patients. It is quite certain to us that there is a definite autonomic nervous system disorder in migraine, and varying proportions of these substances are supposed to regulate the sympathetic-parasympathetic balance. Our figures, however, were not significant of any abnormal variations either between or during an attack. Our data along these lines is to be published shortly.

In considering the treatment of migraine one is reminded of Dr. J. L. Tierney's rueful remark that migraine is philosophically interesting though therapeutically pride-breaking. However, I feel that we can markedly ameliorate the condition. We can make the attacks much less frequent and much less severe.

For the individual attacks the best we can do is to treat them symptomatically. Coal tar products usually in combinations give the best results. The headache is at times so severe that nothing but morphine gives relief but morphine should never be given. A dark room, rest, quiet and resignation on the part of the patient complete the treatment.

But between the attacks a patient should be subjected to an exhaustive examination and all

outstanding pathology should be removed, but the necessity for operation should be weighed with great care. Intestinal hygiene should be the first line of attack. The treatment of constipation will not cure the patient but will contribute to make the attacks less frequent. Emphatically, I do not think there is any special diet for migraine. The diet to be recommended should depend on the abnormal states, if any found such as intestinal putrefaction, fermentation, or cholestasis.

The next line of attack should be directed against focal infection. Abscessed teeth, diseased tonsils, pus in the urine, etc., are definite contributory factors in migraine. Also correction of gynecological abnormalities is of extreme importance.

All this, of course, may be suggested for almost any medical condition, but a vigorous approach is especially important in migraine, because one is working in the dark, as it were, hoping that one may hit upon the irritating factors.

An extremely important duty is to impress upon the patient the realization of his low threshold, and this applies not so much to due to laborious work or exercise as to activities associated with mental and emotional strain.

As to the drugs and medication for migraine, most will be found in the list would include luminal, morphine, atropine, caffeine, strychnine, nitroglycerine, and hypodermic serum, placental serum.

Endocrine glands are of great importance. A remarkable resalman, STANDING COMMITTEES dominating the medical profession in accordance with the medical education in migrain, thorough economic—WILLIAM WARREN BRITT, M.D. Tonawanda as an advertisement.

## OFFICERS OF COUNTY MEDICAL SOCIETIES

The County Medical Society is the unit of organization of the Medical Profession of New York State, and its President, its Secretary, and its Treasurer constitute the County Society in all matters in which any one has dealings with the Society. A correct list of these officers heretofore of great value. Such a list is published on advertising page xxx of this JOURNAL. This, the fifth issue of the JOURNAL since the officers for 1927 were inaugurated, is the earliest issue in which the list could be published, because

the lists of some societies were received only recently.

The officers of many County Societies have also omitted to send news of the meetings. Those of only twenty-nine societies were received during 1926, and every one that came in was printed.

News of the County Societies should be one of the most important features of this JOURNAL, especially when the societies do good scientific work, or take progressive actions.

migraine may have an attack due to constipation at one time, emotional stress at another, or carbohydrate excess at another time. In short, removing the immediate exciting cause will almost never entirely effect a cure. The medical histories of some of these patients are pitiable indeed. Frequently they have run the gamut of medical and surgical specialists, they are wearing glasses, have had two or three nasal operations, have borne with great patience all kinds of diets, possibly have had their appendices and gall-bladders removed, and yet they still have their headaches whether the theories of migraine which seek a or other fundamental explanation must have merely

**Economic interest.** Only two need our attention, have that migraine is a manifestation reduction of the tubercles of the cerebral circulation, though we have every reason to believe that this reduction, the question is, have we or anemias done our part in every instance to prevent the spread of this disease?

None of us deny that tuberculosis is a communicable disease, yet we may hesitate to encourage or carry on a study of conditions which have been instrumental in making our patients ill. When practicing physicians discover a case of tuberculosis, they rarely have the time necessary to conduct an epidemiological study. If they find it impossible to conduct such a study, they should seek the assistance of the public health nurse, through the health officer or the superintendent of the county sanatorium, if one be located in their county. A thorough study of family and other contacts will many times be the means of discovering the focus from which this disease has been transmitted. A child with tuberculous glands may respond to treatment resulting in apparent cure, and surgery or extension of disease is avoided. However, unless the focus from which this child received the infection is removed, other children may become victims of the disease with fatal results. Many times this focus is in an adult member of the family who is ignorant of the presence of any disease. Proper investigation and recommendations may not only be the means of eliminating further spread of infection, but many times will be instrumental in securing treatment for such a person.

Physicians in private practice can do much to assist the public health officials in placing New York State in the lead in this phase of public health, by reporting promptly to the local health

dominating. It is to be recalled that the hypophysis, in association with the thyroid and the suprarenals, stimulates the sympathetics, a suppression of its activity leading to vagotonia. An attack of migraine would be considered an attempt on the part of the hypophysis to assist the control of sympathetic system when it becomes too attenuated.

We have X-rayed a large series of sella turcica in these cases. The X-ray technique of taking the sella is variable, the apparent size of the sella being dependant almost entirely on slight variations of focal distances and angles. Besides no mathematical method of comparing the size of sellas as they present themselves in X-rays has been worked out. However, it is our distinct impression that the sellas in migraine patients are predominantly small, giving little room for expansion except upward. When an extra demand is made on the pituitary for an increased output of its secretion it has little room for expansion in a small

sugg (a) true that while pregnant women are apt to physicians attacks of migraine, their pituitaries medical societies larger in size and weight. But this cal health officer slow process in pregnancy and carried out in cooptoms, just as slow-growing partment of Health, they do not cause disorders State Committee on Health, and by local tuberculosis cal health officers, county normal, consider others.

## WEIGHT REDUCING

Physicians and dictators of fashion both decree that slimness of figure is correct for health as well as good looks. How to reduce weight is an approved topic of parlor conversation, and the popular answer is, to avoid fattening foods, and foods which are "rich," whatever that means.

The people expect to achieve slimness and long-windedness by doing a brief penance of self-denial of one or two beloved dishes, but the problem is not so simple as that, to reduce weight is a difficult and complicated process, and often dangerous. It involves the application of psychology as well as food composition. The physician who undertakes to advise a patient how to reduce must be familiar with calories and their production by various foods. He must also know the dangers of too rapid reduction, and be ready to have analyses of the blood and urine made as they are required.

The importance of the subject of weight reduction, and the widespread popular interest in it, has led the American Medical Association to appoint an Adult Weight Conference. Some of the results of the deliberation of the Conference have been the preparation of articles on dieting, which are published in the magazine section of the *Sunday Herald Tribune*. The one on February 20 was by Dr. Thomas D. Wood, Professor of Physical Education, Columbia University. The article gives sample diets which any one wishing

to reduce may follow. But the essential part of the advice is that any one seeking to reduce in weight should do it under the care and direction of a physician, and after a physical examination.

There is a two-fold obligation implied in Dr. Wood's paper. First, to the patients to go at the dieting problem intelligently, and according to the principles of scientific medicine, and second, to the physician to prepare himself to give the proper advice scientifically and medically.

The question has arisen whether or not the giving of dietetic advice is to be considered the practice of medicine. It is the practice of medicine to prescribe a diet to contain a certain number of calories, even when the preparation of the diet is left to the patient.

It is notorious that the usual methods of reducing weight lead to weakness and fatigue, because of the lack of essential food elements. It is perfectly possible to reduce at the rate of two pounds a week with only slight discomfort from hunger, and with an increase of strength and comfort.

Any one who does periodic health examinations efficiently must needs know how to advise a patient to reduce in weight with safety and comfort, for over-weight is one of the fundamental conditions which affect health and strength and longevity.

---

## THRIFT WEEK

Physicians, as well as others, need to keep clearly in mind certain principles on which financial independence is based. These are well stated in the *New York Herald Tribune* of January 14, Commenting on the National Thrift Week, January 17-23, the newspaper suggests that the semi-annual dental inspection and the annual physical examination be supplemented by a personal economic audit and the correction of financial defects which may be found. It offers the following plan:

"Every citizen is urged to measure himself by the *Ten Point Creed*, upon which the thrift movement is based. One may learn his own economic efficiency by giving himself credit for ten per cent of each of the following points which he

follows with conscientious thought and business acumen:

- 1 Work and earn
- 2 Make a budget.
- 3 Record expenditures
- 4 Have a bank account
- 5 Carry life insurance
- 6 Own your own home
- 7 Make a will
- 8 Invest in safe securities
- 9 Pay bills promptly
- 10 Share with others"

This is a simple creed which every physician may be proud to follow, and which most physicians do follow in a manner befitting their education and standing in the community.

---

## THE PEOPLE'S PART IN THE PRACTICE OF CIVIC MEDICINE

Doctors are sometimes criticized for their inability to prevent the onset of diseases. It is the doctors' work to point out the way of prevention, it is the people's work to follow that advice.

It is beyond human possibility that doctors can set forth the dangers of illness and the beauties

of strength and vigor so forcibly that all the people will feel compelled to follow their advice. If the doctor warns the people and offers himself as a guide on the way to safety and health, he has done his part fully and well. The people themselves must do their own walking down the

## THE LAENNEC EXHIBIT

The New York Academy of Medicine has an exhibit relating to Rene Theophile Hyacinthe Laennec, who, one hundred and ten years ago, invented the stethoscope—the distinctive insignia and equipment of the modern physician and the revealer of internal functions of the living body.

The distinction of Laennec is that from his brain there sprang full grown a new branch of medicine, that of physical diagnosis. One reading his books gets the impression of modernity, even to the nomenclature of the physical signs.

Laennec was a profound student of pathology, and an expert in the art of practicing medicine. He coordinated the findings of the autopsy and operating rooms with those signs which may be discovered on the living body. He was a musician and a poet, and he adapted his keen ear and his gifted imagination to the development of a new art of which the stethoscope was the symbol and the practical instrument of precision.

The Laennec exhibit occupies a long glass case extending across the library of the Academy. It contains about seventy-five articles, mostly editions and translations of Laennec's books. His principal work was entitled "Medial Auscultation," and covered the diagnosis of diseases of the heart and lungs. He says that the idea of the stethoscope came to him while he was attempting to listen to the heart of a fat woman. He recalled seeing some children amusing themselves by applying a stick to the ear and listening to scratchings done on the other end which were inaudible to the naked ear. He rolled a sheet of paper into a tube and through it found that he could hear the heart sounds with magnified distinctness.

Laennec's stethoscope consisted of a short hollow tube about twice the size of a lead pencil, and with a shallow cup on each end. There are

physicians today who prefer this form of stethoscope to the form ordinarily in use.

The principal events of Laennec's life were as follows:

1781—Born in Brittany

1795—Began to study medicine at Nantes

1799—Army surgeon in a Nantes military hospital

1801—Resumed his medical studies—this time in Paris

1802—First medical publication—on the ossification of the mitral valve

1804—Graduated from the Paris Faculty

1802—Pathological studies

1814-16—Assistant physician at the Salpêtrière.

1816—Chief of the medical service at the Hospital Necker, and invented the stethoscope.

1819—Published the first edition of "Traité de auscultation mediale."

1820—Retired for a rest

1822—Returned to Paris and was made professor of medicine in the Collège de France.

1824—Married

1826—Published a second edition of his great work.

Laennec died in 1826 at the age of 45 of pulmonary tuberculosis. He himself says that he considers that he caught the disease through a finger which was infected while doing an autopsy, and which developed a mass of tubercles.

Laennec was learned in the classics. He wrote Greek and habitually used the Latin language in teaching his pupils. Although he was small in stature—five feet three inches tall—yet his personality and attainments commanded the respect and love of his associates, and the reverence of all physicians through the succeeding years.

## BLEEDING IN THE TREATMENT OF GEORGE WASHINGTON

The charge has frequently been made that physicians were responsible for the death of George Washington because they treated him by excessive bleeding. The abstract of an article by Dr. W. A. Wells, printed on page 258 of this JOURNAL, shows that Washington suffered from acute edema of the larynx—a condition for which bleeding was the only known remedy at that time.

There is a scientific foundation for bleeding. A depletion of the fluids of the body is likely to cause the absorption of the fluid from the edematous larynx. The experience of eminent physicians proved that this expectation was sometimes realized. However, a modern physician, knowing the virulence of the streptococci, could not expect the subsidence of the edema to cure the patient,

for the virulent toxins would still remain in the body.

The truth is that the physicians who treated Washington applied the best medical skill available at the time. The bleedings which they performed were based on scientific facts which today are recognized as sound. Bleeding today is recognized as a desirable procedure which physicians do not apply, even in suitable cases, because of the sentimental objections to its application by both physicians and laymen.

The scientific basis for bleeding is discussed on page 234 of this JOURNAL, in a review of a book describing the diseases prevalent in Dutchess County ten years after the death of Washington.

## MEDICAL PROGRESS

Waves of Disease—H Curschmann refers in this article to peaks in the graphs of disease incidence which occur in all maladies irrespective of cause or nature. Their study was begun many years ago by Juergensen. To take the incidence of a given disease—pandemic influenza for example—the recrudescence seems associated with the birth of a new generation without any acquired immunity. In the case of pernicious anemia, on the other hand, we note a sudden jump in 1915-16 followed by a still larger one in 1925. To what may we attribute these increases? Not the war and post-bellum hardships because the rise is seen in other countries which did not participate in the war. Do we have to think in this connection of a contagious element? For the present Curschmann gives up the riddle as insoluble. A similar increase has been noted in some of the acute leucemias, but the obscurity as to the cause is the same here as in Biermer's disease. That two groups of blood disease happen to show the same increase should, but does not, throw any light on it. At the same time chlorosis is showing a striking falling off, which indeed was noted as far back as the end of the last century. A graph quoted shows that in reality a sharp drop occurred in 1893 with a slight temporary rise at the beginning of the century followed in turn by a further steep decline until today the disease is almost extinct. The falling off in a disease once so common is a mystery to most clinicians, although Deneke shows with some plausibility that the trouble increased with tight lacing and declined when the women abandoned this custom. Contributory factors of the same type are plentifully evident as in movements toward open air, exercise, sensible clothing. However, by investigations among certain industrial classes, as the Polish reaping women who still show some chlorosis, it seems to be premature to claim that women can get rid of chlorosis by leaving off corsets and living out of doors, while in a comparison of the curves of corset wearing, etc., with the curves of chlorosis incidence there is no close correspondence seen, so that Curschmann abandons the teaching of Deneke as ill founded. We next have to speculate on whether some mutation of the human constitution has at the same time caused chlorosis to give place to several much more serious blood states. The factors which we have to analyze in this connection are feeding habits and other customs which make up civilization, psychic factors, various infections and climatic and meteorological conditions. We see in the industries how conditions like lead poisoning come and go, because we know the causes and the prophylaxis, but in the diseases which we do not

understand similar causal agencies obtrude themselves and then vanish. Climatic factors may influence cell permeability in a way which, while its other effects are not obvious, may play a great rôle in disease. This great factor is the one which is the hardest to understand and control, and this difficulty handicaps us greatly in a study of the other factors—*Muenchener medizinische Wochenschrift*, December 31, 1926

Cold Feet as a Pathological Condition and Cause of Disease—A Brauchle has written a monographic article on this subject which does not lend itself to summing up in a brief abstract. The latter may therefore be restricted to the subject of prevention and treatment. If the condition is congenital it is a mistake to use warm or hot water to offset it or to make use of heavy footwear or depend at night on the hot water bottle. Instead the feet should be bathed cold and rubbed warm beforehand. The shoes should always be warm and tight but the stockings loose-meshed and changed often. In warm weather the thinnest footwear is allowed with going barefoot when practicable. The child should be about as much as possible and in study periods should be allowed to get up and run about. Exercises, such as rising on the toes, are recommended. Many other hygienic suggestions are given which apply in general to adults as well as to children. The management of the cold damp foot is very similar. The mechanism of cold feet involves a vicious circle, there being an excessive loss of heat without the reactive hyperemia which should follow. In the cold feet of the neurasthenic and hysterical there is also a state of angiospasm. The conditions to which cold feet may contribute are manifold—all of the catarrhal and exposure diseases, the neuralgic and rheumatoid, etc. In a diphtheria epidemic the cold-footed children are the first to be attacked. Engelmann has sought to uphold the existence of a law that the more remote the organ from the feet the more apt it is to suffer. If this is so, one would expect cranial neuralgia and rhinitis to be more common in these subjects than enteritis or cystitis—*Muenchener medizinische Wochenschrift*, December 3, 1926

Urticaria from Cold—G B Podestà of the neurologic clinic at the University of Genoa relates two cases in which the application of cold produced locally wheals and constitutionally the hemoclastic reaction of Widal. In fact Widal and Abramì reported a case of urticaria from cold which is of the same type as the author's material, save that the exposure to

straight and narrow way to health and strength

The physicians of New York State offer to immunize the people against diphtheria, the acceptance of the offer requires an immense amount of persuasion and instruction by school teachers, public health nurses, and other lay workers

Rabies has been certified by the State Commissioner of Health, Dr Matthias Meade, Jr, in several communities of five counties, but the out-

cry against impounding pet dogs straying on the streets is apparently louder than that of the advocates of protection

Are doctors responsible for the ignorance and apathy of the people in public health matters? Not in these days when health lectures and radios, and especially newspapers carry health information in far greater quantity than the people can assimilate

## LOOKING BACKWARD

This Journal Twenty-Five Years Ago.

The Smallpox versus Dr Pfeiffer — This JOURNAL for March, 1922, contains an article describing the contraction of smallpox by Dr Pfeiffer, an anti-vaccinationist of Boston —

"A smallpox case destined to be famous in the history of the progressive victory of therapeutic science over the ranks of ignorance, prejudice, quackery and sentimentalism is that of Immanuel Pfeiffer, M D, of Boston and of Bedford, Mass This physician was certainly one of the most vigorous and intelligent of the anti-vaccinationists, yet he was very certain, in his own mind, that small pox is not a contagious disease, but that it is rather the product of bad hygiene and evil diathesis

"Dr Pfeiffer has been for many years emphatic in his denunciation of vaccination He deemed it always an injury and never a benefit, but he denounced it especially because he considered compulsory vaccination a violation of the rights of the individual, however strikingly obvious such rights may be of the undoubted rights of others, far more numerous, in their demand to be protected by the State from all preventable disease

"Dr Pfeiffer, to his honor be it said, had the courage of his convictions on this subject, and in this respect at least he differed from the great majority of his cult During a recent anti-vaccination hearing before a committee of the Massachusetts Legislature he undoubtedly determined to prove that to a person in vigorous health, as he himself then was, smallpox is not a contagious disease This fact he hoped to demonstrate and he chose the means best adapted certainly to make his expected demonstration publicly emphatic To obtain permission from the Boston Board of Health to visit the numerous patients in the city's smallpox hospital on Gallop's Island was for him, as for other physicians, a comparatively easy matter

"Permission was readily granted, and on January 23d, well escorted by officials of the

Board, he visited the hospital He thoroughly examined the institution, and went to the bedside of many of the patients, and he took all precautions which other visitors take to avoid infection (such as wearing of a close-bound gown and cap, washing the hands, beard, hair, etc., on leaving), save that of vaccination

For the next ten days, more or less unknown to himself, he was watched and attended by physicians from the Board of Health in order that the public might be protected from infection from his anticipated disease During these ten days he was at his office and in the anti-vaccination hearings, as was his wont But on February 3d, ten days after his visit to the hospital, when the officer called at his professional office on Washington Street, Dr Pfeiffer was not to be found, nor did he appear at the State House hearing

"On the following Saturday, fifteen days after the visit to Gallop's Island, the Boston Board of Health received notice from a physician that Dr Pfeiffer was ill at his home in Bedford with what was probably smallpox, and asking expert diagnosis, the case having been reported by Dr Pfeiffer's son to the Selectmen of that town Experts went at once to Bedford and found Dr Pfeiffer suffering from a very bad attack of the disease

"The latest news from the bedside of this for once useful anti-vaccinationist is that he may recover, although he is suffering from the confluent type of the disease All hope that such will be the case In the event that this wretched malady leaves him alive, we may perhaps expect from him one of three things—either that he will deny that his disease was smallpox, or that he will relinquish his public opposition to a world of demonstrated medical wisdom, or that he will admit that smallpox is contagious and that the public therefore needs protection from its awful ravages by any and every feasible means"

sician, mentions a case in 1912 in which a child who had been treated in an isolation institution was allowed to return home with a running ear after a six weeks isolation. A few days after its return the father developed a scarlatinal angina which proved fatal. Recently the author has had a similar case in which a boy of 8 years was allowed to return home after six weeks isolation. Desquamation was over but an afebrile otitis media was just beginning. He was forbidden to return to school and automatically went back to the care of the family physician, who forbade to the four younger children attendance at the school and kindergarten, and to them and the mother alike attendance at public gatherings. There was no household quarantine. Nothing happened until the rupture of the tympanic membrane in the convalescent boy, whereupon a three-year old sister promptly developed the disease and was taken to the hospital, where she was soon followed by a seven-year-old brother. This episode taken in conjunction with the earlier experience appears to show that the pus of scarlatinal otitis is actively contagious with a very short latent period of one to two days, and that in these postscarlatinal otitides the isolation period should be prolonged until there is no longer risk of contagion. The author advocates a routine isolation of seven in place of six weeks independent of the ear complication. He could find no possibility of any other source of infection of the two return cases.—*Deutsche medizinische Wochenschrift*, December 3, 1926

**Treatment by Drugs**—In a presidential address to a Branch of the British Medical Association, H. Guy Dain (*British Medical Journal*, December 25, 1926, ii, 3442) takes exception to the tendency to regard the use of drugs, with the exception of those known to be specifics in the treatment of certain diseases, as in the main unnecessary and useless. This has not been his experience. He first mentions the diminishing use of opium, and states that he always experiments with combinations of other pain-relievers as long as possible before resorting to the use of this drug. In a few cases of inoperable carcinoma he has found useful a formula containing magnesium carbonate 5 grains, potassium citrate 5 grains, alum sulphate 2 grains, tincture of opium 2 minims. In acute "cold in the head" a few doses of ammonium chloride 10 grains, sodium salicylate 10 grains, chlorodyne 10 minims, produce almost magical results, but with the constituents tried separately the same effect cannot be obtained. In acute pneumonia it is dangerous or even fatal to give saline aperients, especially magnesium sulphate, expectorants are almost equally undesirable, as they increase the risk of the condition in which the patient literally drowns in his own secretions. In the early stages Dain pre-

scribes quinine and calcium chloride, hoping to keep the air-passages dry, with the addition of opium when there is much pleuritic pain. In epidemic influenza earlier relief of symptoms is afforded by the use of quinine and aspirin. In an advanced case of alcoholic cirrhosis of the liver with ascites, aspirin caused diuresis and made further tapplings unnecessary. Also in a case of tuberculous peritonitis the administration of salol acted like a charm, the fluid and symptoms disappeared and the patient has remained well for fifteen years. Salol is useful in conditions of intestinal catarrh or diarrhea, alike in small children and in older people. In mucous colitis, besides the salol, liquid perchloride of iron, liquid perchloride of mercury, and tincture of hyoscyamus, of each 15 minims, taken half an hour before food, give excellent results. Not all patients, however, respond to this. In severe and prolonged cases great benefit may be derived from iron and ammonium citrate 5 grains, liquor hamamelidis 15 minims, tincture of opium 2 minims, the opium being omitted when pain and diarrhea are not present. In cases of "nerves" potassium bromide 10 grains with liquor strychninae 3 minims [ $\frac{1}{35}$  grain strychnine hydrochloride] is helpful. In the vomiting of pregnancy a mixture of sodium bicarbonate and bismuth with the addition of bromide is most effective. In the treatment of failing heart muscle Dain has had good results with the administration of adrenaline by mouth, in spite of the fact that we are told that it is only effective when given hypodermically. Among effective tonics which are not expensive are strychnine hydrochloride with chloroform or peppermint, or Easton's syrup [syrup of phosphates of iron, quinine, and strychnine (N F)], 30 minims in water.

**The Rationale of Foreign Protein Therapy**—Dr. C. Mez, a botanist, seeks an explanation of the good results often obtained from the injection of foreign protein. For the past 16 years much experimental research into medical subjects has been carried on in the Königsberg Botanical Institute, for while the research is botanical in method and aims it has a strong bearing on medical problems. Freund has already pointed out two wholly distinct effects of foreign protein injection. One, of course, is stimulation or irritation, for foreign protein of any sort possesses this property while the other, which appears later, is toxic in character. This distinction is fully in accord with the author's viewpoint. He finds that the initial stimulative action increases the production in the blood of an enzyme which breaks up albumin and is nonspecific in character. This enzyme is normally present in slight degree and its function is to disintegrate albumin after cell death and thus detoxicate it. In the second stage of the process the antigens which appear in the blood form antibodies which

cold was general and not local. Mibelli reported cases similar to the author's in 1923 and other references are given in the bibliography but are not mentioned in the text. It is certain that the condition is extremely rare and it does not appear to possess any special clinical importance. The first patient was 32 years old when first seen and his peculiarity did not manifest itself until two years previously, although he must often have been exposed to cold from his occupation of sailor. The wheals and pruritus appeared on the exposed areas—face, hands—and were burdensome. The author tried to immunize him by injecting calcium chloride and his own blood but the benefit derived therefrom was not permanent. The other patient was a middle-aged woman who had developed her peculiarity four years before consultation. Her face and hands were the seat of urticaria whenever she washed them in cold water. It was in this patient that blood studies showed the presence of the colloidoclastic shock. The patient also exhibited dermatographism with red wheals, and many vasomotor phenomena were manifested after the exhibition of alkaloïds, endocrine substances, etc. It does not appear that any exact diagnosis was made or any benefit from treatment obtained, although the author speculates extensively on the nature of the peculiar humoral state.—*La Riforma Medica*, November 15, 1926

**Status of Chemotherapy**—B. Nocht of Hamburg, writing in a supplement to the *Khnusche Wochenschrift* of November 26, 1926, gives a comprehensive summary of our progress in this resource, using the term in the sense of specific activities directed against the causation of the disease, conceived as a bacterium, a protozoon, etc. Much that is called chemotherapy does not come under this conception, but anthelmintics, insofar as they are chemical substances given to destroy nosoparasites, do belong here. Antibacterial therapy is discussed first and while many chemical substances are employed for the internal treatment of germ diseases the results obtained have not yet proved of revolutionary significance, as is readily seen when we compare them with the results obtained in the treatment of diseases due to spirochetes and trypanosomes and even to fungi. The action of iodine in actinomycosis and sporotrichosis is, however, not exactly chemotherapeutic in the strict sense of the term, for in the author's opinion it merely removes the product of the disease without attacking the cause. The great triumphs of chemotherapy are seen in connection with syphilis and frambesia, African sleeping sickness, the leishmanioses, amebic dysentery, and malaria, and their treatment with arsenicals, antimonials, emetine, and quinine. Two other

protozoan affections may be added to the above—epidemic relapsing fever and the contagious pneumonia of horses, although in the latter it is rather the prophylactic than the curative property of salvarsan which is concerned. But certain diseases of spirochetic origin, as yellow fever and Weil's disease, fail to respond to spirillicides. The arsenical synthetic "germanin" appears to be able to control the South American horse plague known as mal de Cadera, and it is said to be equally efficacious in the trypanosome disease of the camel.

**A Comparison of the Effects of Supplementary Feeding of Fruits and Milk on the Growth of Children.**—Agnes Fay Morgan, Glatha D. Hatfield, and Martha A. Tanner (*American Journal of Diseases of Children*, December, 1926, xxxii, 6) report the results of observations made on 47 children living in the California State Schools for the Deaf and Blind, where the house diet was excellent, though somewhat deficient in raw fruit. The children were divided into four groups, those of one group receiving as a supplementary lunch one half pint of milk, those of the second group a medium orange each, those of the third group four pulled figs each, while a fourth group was used as a control. The results of these additions to the diet were judged by the Baldwin-Wood, the Pirquet, and the Dreyer standards. The percentages of the original groups showing increases, after fourteen weeks, in standing and sitting heights were greatest in the milk group, in chest circumference, chest expansion, and vital capacity in the fig group, and in hand-grip strength in the orange group. The average of all measurements showed the number of increases in the fig group to be the largest. A possible correlation is suggested between the increase in chest measurements of the fig group and the increased carbon-dioxide capacity of the plasma resulting from the excess basicity of the fig ash and its laxative value. An average of all the gains showed the orange group first, the fig and milk group next, and the control group last. The gross average gain in pounds was greatest for the milk group, and the average percentage gain in weight above that expected, according to the Holt standard, was largest for the orange and milk groups. At the end of fourteen weeks 7 children were changed from milk to orange, and 7 others from orange to milk, and the feeding continued four weeks longer. The average rate of gain in weight was considerably decreased in those changed from orange to milk, while those changed from milk to orange were very little affected.

**Duration of the Transmissibility of Scarlet Fever**—E. Bernhardt, a Berlin school phy-

Counsel Medical Society of the State of New York

## THE HAZARDS OF MALPRACTICE SUITS

The hazard of malpractice actions for the physician was again brought forcibly to the attention of the writer through a recent decision of the Supreme Court of Wyoming in the case of *Phifer against Baker*. In that case a child aged nine years sustained a fracture of her left arm between the wrist and elbow and charged negligence on the part of the defendant doctor in bandaging the arm too tightly at the time of the first treatment and refusing to loosen the bandages. A verdict of Ten Thousand Dollars was recovered and was sustained by the Court of Appeals. And recently in New Jersey a judgment for Thirty-five Thousand Dollars for the alleged malpractice of a physician was recovered.

The hazard of malpractice is with the physician always. While we have great faith in the jury system and believe that in the long run justice is obtained in the courts, the fact remains that in each case the conduct and treatment of a physician is the subject which twelve ordinary laymen are authorized to pass upon.

Of course it is obvious that many times very bad results are obtained through no fault or negligence on the part of the physician, and yet oftentimes these results are so impressive that there is always the danger that a jury may be swayed by sympathy with the patient and may conclude that the undeniably bad result has been occasioned through the doctor's fault. In cases where the facts are in dispute, there are instances in which the verdict of the jury (the jury being the sole judges of the facts), must be upheld by the higher courts, even though the verdict is so large as to result in the impoverishment of the defendant.

Recognizing these truths, the group plan of insurance was inaugurated by the New York State Medical Society some five years ago. It has been operated with signal success and with the approval of all those who have availed themselves of its benefits. To a doctor who is harassed and perplexed and worried and concerned over a malpractice action in which he finds himself the leading character, there is a peculiar comfort which comes from the knowledge that if the verdict goes against him the judgment will not be paid by him, but by the insurance with which he has been foresighted enough to protect himself. Despite these facts, cases are constantly arising in which doctors have not protected themselves by insurance and in which it is always possible that a verdict might be rendered which would result in heavy financial embarrassment if not in financial ruin.

During the last month your counsel had the pleasure of vindicating, in a very serious malpractice suit, the rights of one of the leading obstetricians of the metropolitan district. The case was one in which the child had lost the sight of one eye through ophthalmia neonatorum. The claim of the plaintiff was that the doctor had failed properly to treat the eyes of the child at birth. In this case, had the jury decided against the doctor, a verdict in a very substantial amount would have been the result. The doctor was financially responsible, but such a verdict would have been a serious blow to him, not only from the standpoint of his professional standing, but to his pocketbook as well. This particular physician is now insured under the group plan, but his insurance was not taken out until after the occurrence which formed the basis of the suit. The feelings which this member of the medical profession suffered during the three days of the trial are such as your counsel would be glad to have other physicians avoid. The doctor knew that an adverse verdict would involve consequences of the gravest character and he knew also that had he been insured, at least the financial onus would have been borne by the insurance carrier rather than by himself. Fortunately, a verdict was recovered from the jury in behalf of the defendant, thereby vindicating him in his practice and avoiding any financial loss. This satisfactory result, like so many which we have been fortunate in securing, cannot, however, be anticipated in every case.

Every malpractice action presents a serious risk to the physician and such a source of worry as those only who have faced one fully understand. The means whereby the crushing load of financial worry may be lifted from the shoulders of the doctor sued for malpractice was earnestly sought by your State Society and its officers five years ago. They met and solved this problem through their inauguration and maintenance of the splendid group plan of insurance, which in every detail has justified all the hopes which were entertained for its success.

From experience in hundreds of cases, your counsel is at a loss to understand how any physician is willing to assume the grave financial risk in the practice of his profession without protecting himself through the medium of the Society's highly satisfactory group plan.

In numerous instances where physicians have seen fit to take out insurance in companies other than that in which the State Society's group plan

are specific. In other words, the enzyme digests the antigens with production of the antibodies. Buchner has said that an antitoxin is nothing but a toxin made harmless—detoxicated. This view is opposed to the common belief that an antitoxin is a product of the patient's own blood albumin, which the author regards as quite untenable. The real defender of the patient is the enzyme produced in excess by the presence of the foreign substance and the real immunization is the transformation of the antigen into a harmless substance.—*Muenchener medizinische Wochenschrift*, October 29, 1926

**Treatment of Infantile Rickets by Intramuscular Injection of Cod-Liver Oil Concentrate**—Lawson Wilkins and Benjamin Kramer administered to two children with active rickets a concentrate of cod-liver oil by the intramuscular route at weekly intervals, in doses equivalent to 25 cc of the oil. Fresh calcification of the rachitic cartilage appeared within three weeks. The changes in the concentration of calcium and inorganic phosphorus of the serum were identical with those previously observed following the oral administration of cod-liver oil. Whereas cod-liver oil increases the absorption of phosphorus and calcium from the intestine, as shown by Howland, the fact that it is effective when administered intramuscularly indicates that it is not purely a local action upon the intestinal mucosa but is a general one and exerted through the circulation. In preparing the concentrate cod-liver oil was saponified by means of alcoholic potash and extracted with petroleum ether. One cubic centimeter of this petroleum ether is equivalent to 1 cc of cod-liver oil. The dose to be administered was measured into a dish and the petroleum ether allowed to evaporate in the air. The solid residue, redissolved in ethyl ether, was injected into the gluteal muscles of the patient.—*Bulletin of the Johns Hopkins Hospital*, January, 1927, xl, 1

**Treatment of Raynaud's Disease**—E. P. Poulton, writing in *The Lancet*, December 18, 1926, ccxi, 5390, advises in the milder cases attention to the general health and the application of simple local measures, such as rubbing the hands, bathing them alternately in hot and cold water, the wearing of gloves, together with large draughts of physiological saline solution in the early morning. Galvanic electricity, high frequency currents, and diathermy may also be of value. In the more severe cases, especially when gangrene threatens, Einhorn's treatment should be adopted. This consists in the administration of large quantities of sterile saline solution (0.85 per cent) at body temperature through a duodenal tube. The tube need not enter the duodenum but should be introduced to the 28-inch mark. With the patient on his right side, two

pints of saline are run in, and subsequently one pint every half hour, until 8 to 10 pints have been administered. The treatment may be carried out for four or five days in the week for a period of two or three weeks, watching for pulmonary edema, which sometimes occurs. Tomnek of Prague uses intravenous injections of radium emanation in physiological saline solution, the dose being 2 to 3 millicuries, gradually increased to 15 millicuries. He suggests that radium is an antagonistic to adrenaline which is responsible for the spasm. Surgery is to be considered only in the most intractable cases. The methods that have been employed include that of Lenche by which the periarterial sympathetic nerves around the femoral artery are removed, injection of alcohol around the artery, and more recently the method of Davis and Kanavel which consists in the removal of the lower and middle sympathetic ganglia of the sympathetic chain of the neck. The oxygen bath is valuable and has not been sufficiently employed. The limb is placed in a wide-mouthed rubber bag, which is filled with oxygen and bound air-tight on the limb above the affected part. Amputation should never be resorted to unless the whole end of the limb is becoming gangrenous.

**The Malaria Treatment of Early Syphilis**—F. Bering would not submit all victims of early syphilis to inoculation with malaria virus, but if there were a positive Wassermann in the cerebrospinal fluid at the close of the regular treatment—say about the end of the two-year period following infection—he would feel justified in taking this step for the prognosis would justify it, even if the positive test were feeble. This condition he would attack with arsphenamine, mercury, or bismuth, for this course can clear up the liquor and he would combine the three remedies in the same treatment, but if the liquor then reacted positively he would go over to the malaria treatment. The first to make use of the latter in comparatively early latent syphilis was Kyrle and the author has followed his technique, including an intravenous injection of quinine to cut short the malarial infection. The author has now treated 137 patients with manifest or latent syphilis within the first two years after infection or latent syphilis within the first two years after infection. The puncture of the spine to test the efficiency of the cure should not take place until after the expiration of four months. All of this series were submitted to the puncture and while the author gives no figures he states that the results were very satisfactory. In some of the manifest cases syphilides which had been rebellious to regular drug treatment disappeared promptly under the use of the malaria virus. On the completion of the malaria treatment the author adds a course of arsphenamine.—*Muenchener medizinische Wochenschrift*, November 26, 1926

supported and held in place with adhesive plaster. The patient was put to bed with ice compresses to nose and there were daily dressings for about five or six days. He remained at the sanitarium for about four days following the operation. The patient then returned to his home but came back for daily dressings for about two weeks. At this time no complications of the field of operation were observed and no complaint was made by the patient. He breathed freely through the nostrils on both sides and there was no occlusion at that time.

Thereafter the patient called upon the surgeon once or twice each week for about two months, by which time he needed no further treatment, his nose had healed and he was breathing freely.

The next heard from the patient by the surgeon was when he returned the following June, and upon examination it was found that a keloid had formed at the site where the lateral cartilage had been removed. Under a local anaesthesia the

keloid was removed and the patient remained at the sanitarium over night following the operation. He returned daily to the surgeon for a period of ten days, at each of which times the wound was dressed. Thereafter he was seen by the surgeon twice a week for two weeks. This was the last time the patient was seen by the surgeon.

The action finally came on for trial, the trial of the same consuming three days. Expert testimony by physicians was introduced on behalf of both the plaintiff and the defendant. The plaintiff likewise testified in his own behalf and exhibited himself to the jury, showing the results of the operation, he at that time having a very marked saddle nose. The defendant likewise testified in his own behalf, describing in detail the technic in the performance of his operation and in the subsequent care. After hours of deliberation had by the jury, a verdict was returned by it for the defendant, thus terminating the action in the surgeon's favor.

---

### PREGNANCY—INJECTION OF PITUITRIN FOLLOWED BY ABSCESS

One of the defendants in this action, a physician specializing in obstetrics, was engaged to attend the plaintiff during her pregnancy. It was charged that upon his recommendation the plaintiff procured a room in a hospital conducted and operated by the other defendant, that the physician conducting the hospital had neglected and failed to perform his duties towards the plaintiff so that one of the nurses at the hospital improperly gave the plaintiff a hypodermic injection, causing an infection and an abscess, endangering her life and that of the unborn child, that it subsequently became necessary for the plaintiff to procure other medical and surgical attendance, that the plaintiff became an inmate of another hospital where she remained for a period of about ten days and was not entirely cured until a long period after her discharge from said hospital.

On July 14th the patient, a primipara, had been in labor intermittently all morning and at the time of delivery there was a cessation of labor pains, there was, however, complete dilatation of the uterus, the vaginal canal was clear with the head well engaged. The physician thought that it would probably be necessary to resort to for-

cep delivery. Under his instructions a  $\frac{1}{2}$  c c of pituitrin was hypodermically administered to the patient. There was a spontaneous reaction to the pituitrin and the patient was delivered of a normal child. No tear of peritoneum or laceration of any kind. The patient was returned to bed in good condition. On the day following the delivery there appeared upon the thigh of the patient a large red area. This area of redness continued to enlarge from day to day. No positive diagnosis of the condition was made by the physician who delivered her. After consultation it was thought that the patient probably had erysipelas or an abscess. As there was no accommodation at the sanitarium of which the plaintiff was a patient for surgical treatment, the physician attending the plaintiff suggested and recommended her removal to another hospital. Five days following the delivery the patient was removed in a private ambulance to another hospital where the proper surgical attention could be given her. No further treatment was rendered by the defendant to the patient and nothing further heard from her until the institution of the malpractice action.

During the pendency of this action the defendant died and the action therefore abated.

is carried, your counsel has received inquiries as to whether or not physicians thus insured are entitled to his services. All of them seemed desirous of securing his services. Unfortunately, however, where a physician is insured in a company other than the Society's insurance carrier, such physician cannot secure your counsel's services where the policies in such companies provide that the policyholders must accept the services of the counsel of the company issuing the policy. Thus, so far as is known, is a provision common to all policies.

From a long experience the writer is convinced that no commercial company has ever attained to that complete understanding of the physician's

problems which is possessed by the carrier under the group plan. This company has, and on all occasions displays, complete confidence in your counsel's judgment and never suggests a settlement, nor is indeed willing to make a settlement except in cases where your counsel feels a settlement is justified. In every instance the doctor's reputation and his professional standing are of paramount consideration.

Once again your counsel cannot too strongly emphasize the value of the group plan of insurance and of the importance, to each individual doctor, of availing himself of its inexpensive and highly beneficial protection.

### PLASTIC OPERATION WITH RESULTANT SADDLE NOSE

A young man engaged in the occupation of a photographer had sought advice from the defendant for the relief of obstructed nasal breathing and the correction of a nasal deformity.

In a malpractice action instituted against the surgeon it was charged that by reason of the negligence and carelessness of the surgeon in the performance of the operation too great a quantity of the septum was removed, causing the bridge of the plaintiff's nose to fall, thereby obstructing his breathing to an extent greater than it had been obstructed before the operation and distorting his features and otherwise injuring him in his health and in his occupation and business.

In this action he sought to recover damages for the injuries alleged to have been sustained by reason of the negligence in the operation.

When the patient first came to the surgeon in October, upon examination the surgeon found that the patient had a hook nose hanging down, with a lateral displacement to the left, also a marked deflection of the nasal septum obstructing the breathing space through the nostrils. It was also found that the nasal obstruction was complete producing pressure symptoms and headaches and stagnation of the nasal discharge.

After the examination the surgeon advised the performance of a submucous resection for the correction of the deviated septum, the removal of the hook, the shortening of the nose and the correction of the lateral displacement. The operation was consented to, and after the proper anti-septic preparation and the cleansing of the external parts of the nose, the mucous membrane was cocaineized with a ten per cent solution of cocaine hydrochloride. Adrenalin hydrochloride was applied to control the bleeding and a weak solution of cocaine hydrochloride and adrenalin was injected.

A submucous resection was then performed, an incision being made through the mucous membrane of the left side of the septum, through the perichondrium, the mucous membrane elevated

and the incision made through the cartilage up to but not through the mucous membrane on the right side of the septum. When separation was completed on both sides, the quadrilateral cartilage of the septum was removed with a pair of forceps. The remainder of the obstructing septum was removed in the usual manner with Ritter forceps. Upon the completion of the submucous resection the surgeon then proceeded to the removal of the hook.

Incision was made at the edge of the triangular cartilage on both sides. He freed the subcutaneous tissue from the cartilage and bone. He then sawed inward toward the median line from both right and left side with Joseph bayonet saw. He then freed the sawed-off hook from any remaining attachments with a sharp-edged buckle-pointed knife, then removed, freed and separated hook with a pair of forceps, smoothed the rough edges with a Joseph file and smoothed the cartilage by cutting away in very small strips with a sharp-edged, buckle-pointed knife. In the elevation of the point of the nose an incision was made between the quadrangular cartilage and septum mobilis to free the entire anterior portion of the septum. He then removed the triangular piece of the lower end of the quadrilateral cartilage. He connected the upper freed portion of the septum with the lower incision. He then sutured the new formed lower end of quadrangular cartilage with several sutures.

The lateral displacement was corrected by an incision made into the external lower end of pyromiformis opening on both sides. The periosteum was freed from the bone from the lower external end of the pyromiformis opening to radix nasi, sawed through with a knee-shaped Joseph saw through processus frontalis and osseous maxillaris on both sides, freed portion of bone was bent toward the median line to straighten the lateral displacement and to correct the secondary width of the nose.

The nose was packed with sterile gauze and

he felt there would be very slight objection to the abolition of town boards of health, that even the health officers themselves would in a majority of instances, prefer to work under a county health board

Mr Kingsbury thought the board of supervisors should be given such opportunity

Mr Folks said that Dr Stanton P Hull, president of the New York State Sanitary Officers' Association, believes that his association would raise no general objection to the abolition of county health officers where the county health unit is created

Dr Farmer then called for specific discussion of the question, "Should County Health Units Be Encouraged?"

Dr Britt thought, that in such procedure, the County Medical Society should be consulted first of all, and its reaction ascertained. He wondered what reactions by County Societies have been noted

Dr Brooks stated that the Department of Health's program is, first, to consult with the County Society before anything more is done.

Dr Britt, when asked whether he had any reactions from physicians, offered a number of letters that he had received from physicians in Cattaraugus county in response to a questionnaire he had sent out, from which the following deductions were made

- 1 As to whether there had been a reduction of sickness since the organization of the county health unit—11 physicians replied negatively, while 3 thought there had been.
- 2 As to whether the county health officership operated against the best interests of the physician—12 answered in the affirmative and 2 in the negative
- 3 As to whether it affected the specialist—1 replied enthusiastically in the affirmative.
- 4 As to whether the activity met with general approval—6 thought it did because of the intensive advertising it carried with it. 1 thought the result was indifferent, while 3 did not believe it met with general approval

Dr Williams questioned the value of data collected thus, on the ground that the question of the reduction of sickness was a matter for statisticians to work out and could not be based upon the reports for so short a time as one or two years in one small county

In summing up Dr Farmer said that the creation of county health units, it would appear, would be beneficial and that we should probably consider plans to promote such, that the committee's work would be to help develop a satisfactory plan

Mr Folks offered the following resolution, which was unanimously adopted

"WHEREAS, After a full discussion of the subject of county health units, it was the opinion of the representatives of the State Medical Society and of the State Charities Aid Association, that such units would be desirable for the following reasons

"1 Stimulates idea of local self government,

"2 Permits of more accurate adjustment of budget funds to immediate needs,

"3 Precedent in Department of Education, highways, and tuberculosis work,

"4 Recognized as unit in legislation,

"5 Can afford full time health officer and staff, making possible a health service approaching in adequacy that enjoyed by cities,

"6 Facilitates cooperation with State Department of Health,

"7 Facilitates raising necessary funds,

"8 Would aid community to profit by law which provides state aid in public health activities to counties

"Therefore, Be It Resolved, That we urge the establishment of county boards of health and county health officers in the various counties of the state under the existing enabling law"

\* \* \* \* \*

Mr Folks, speaking on the plans of promoting the creation of county health units, said that his organization approached the county through the local Committee on Tuberculosis and Public Health and, later through the State Department of Health to the County Medical Society

Dr Brooks said that the Department of Health's approach was always through the County Medical Society

Dr Farmer suggested that the Public Relations Committee should consider a recommendation to the House of Delegates that the presidents of the district branches be encouraged to familiarize themselves with the subject of the creation of county health units, and take it up with the counties in their districts

Dr Fisher said that it was his idea that every County Society should take an active interest in the matter and that they should have a Committee on Public Relations always ready to treat with other agencies that would be interested in advancing health activities

Dr Britt announced that a meeting was contemplated for representatives of the County Societies in the Eighth District Branch, at which this subject would be taken up. The Meeting will very likely be held within the next month

Mr Kingsbury suggested that the Governor's conference would greatly stimulate immediate interest in the creation of county health units

After a more general discussion of the position the County Medical Society should take in the creation of a county health unit, the following resolution was framed and offered by Mr Folks

"Resolved, That it is desirable that, when the

# NEWS NOTES

## COMMITTEE ON PUBLIC RELATIONS

The sub-committee of the Public Relations Committee met by appointment with the sub-committee of the Tuberculosis and Public Health Committee, at the Biltmore Hotel, New York City, on Wednesday, February 9, 1927, at 3 P M. The following were present Drs Farmer, Britt, Mr Folks, Mr Nelbach, Dr Williams and Dr Lawrence, also Deputy Commissioner Brooks of the Department of Health, Drs Fisher, Van Etten and Mr J A. Kingsbury.

Dr Farmer announced as the subject for discussion, "The Creation of County Health Units," and urged that the discussion be informal and free, so that the committee could later prepare a report to be submitted to the joint committee on February 24th. He asked Mr Folks to open the discussion.

Mr Folks said that he and Mr Nelbach had prepared some suggestions, both pro and con, with regard to the establishment of a county health unit and, upon invitation he read the following:

### A Points In Its Favor

- 1 Modern public health, a many sided matter of great specialization, and requires a number of different things to be done, *e g*,
  - (a) Consultation service in five or six medical specialties,
  - (b) Communicable disease control,
  - (c) Statistics,
  - (d) Public Health Nursing,
  - (e) Laboratory Work,
  - (f) Public Health Education,
  - (g) Sanitation
- Impossible for state itself to provide all these services in all towns, villages and cities.
- Towns, villages and small cities are all too small to be able to carry on all these activities in its particular area, they could not afford to employ the specialists and agents to provide all these services, nor would there be enough of each kind of work in such localities needing to be done to justify employment of such specialists or agents by such small localities.
- 2 The county, generally speaking, is the local governmental unit best fitted by population and economic resources and by actual experience over a period of years, to provide facilities for meeting modern social welfare needs, *e g*,
  - (a) Almshouse,
  - (b) Jail,
  - (c) Probation system,
  - (d) Children's court,
  - (e) Tuberculosis hospital,

- (f) Laboratory,
- (g) General Hospital,
- (h) Widows' pensions

- 3 Experience in other states has shown that the county is the most practical local unit of health administration, as in Ohio, North Carolina, Alabama and Virginia.
- 4 Experience in Cattaraugus county over a period of four years has demonstrated the suitability of the county as the governmental unit of health administration.
- B *Arguments Cited Against the County Health Unit*

Expense, because under the present statute, the system of town, village and city health units is continued along with the county health unit.

\* \* \* \* \*

Dr Lawrence offered the following points which he had collected with regard to advantages of a county health unit:

- 1 Stimulates idea of local self government
- 2 Permits of more accurate adjustment of budget funds to immediate needs
- 3 Precedent in Department of Education, highways, and tuberculosis work
- 4 Recognized as unit in legislation
- 5 Can afford full time health officer and staff, making possible a health service approaching in adequacy that enjoyed by cities
- 6 Facilitates cooperation with State Department of Health
- 7 Facilitates raising necessary funds

As an argument against the creation of a county health unit, Dr Brooks suggested that supervisors are likely to be more political than members of a town board.

Mr Kingsbury took exception to this and stated that in his experience boards of supervisors have shown themselves to be very deliberative bodies, comparing favorably with the larger legislative units.

Dr Farmer asked whether it is the intention to abolish local health officerships.

Dr Brooks said that the Department of Health had considered introducing to the law a permissive clause for such action by county supervisors. He felt that, in some instances, the supervisors would want to abolish the town health officers on the ground that their maintenance in conjunction with county health officership is too expensive. The district state health officers, he said, are of the opinion that, in general, there would be violent objection to the abolition of county health officerships. He said further that

Dr Wells discussed the criticism that the bleedings killed the General. Bleeding was the standard procedure of the day, and doctors would not have persisted in doing it if had been often attended with bad results.

Dr Wells also discusses General Washington's previous health history. His father had died at the age of 49 from an affection similar to that of the General. His grandfather died at the age of 37, and his great-grandfather, at 54. Nearly all the other known members of the Washington family were short lived, but his mother was 82 when she died.

Washington has a severe attack of smallpox which he caught in the Barbados where he had gone with his brother, Lawrence, who seems to have had tuberculosis. Soon after his return from the Barbados, he had "a violent attack of pleurisy, which reduced me very low."

During the Braddock campaign, he developed an unknown fever, which his servant also had.

Two years after the Braddock campaign, while he was still doing frontier work with the army, Washington had a severe attack of dysentery, which compelled him to return home. He suffered from recurrent attacks of the disease for some months.

In 1761, Washington had a fever, probably malarial. Dysentery recurred in 1768, and kept the General in the house for a week.

Washington had malaria in 1786, and was relieved by "Bark" administered by Doctor Craik.

In the late spring of 1789, Washington had a severe carbuncle on his left hip, which kept

him in bed for six weeks, while he was treated by Dr Samuel Bard.

When Washington visited Boston a little later he caught a troublesome cold with inflammation of his eyes. This form of sickness became prevalent throughout the city, and was called the "Washington influenza."

In 1790, Washington had pneumonia in Philadelphia, in which he suffered two relapses.

In 1793, Jefferson wrote to Madison, "The President is not well. Little lingering fevers have been hanging about him for a week or ten days, and affecting his look most remarkably."

In August, 1799, he wrote of "Debilitated health occasioned by the fever which deprived me of 20 pounds of weight."

Washington began to have trouble with his teeth before 1754, and he lost them all and replaced them with a false set at a comparatively early age. He began to use glasses at the age of 46. He was noticeably hard of hearing during his later years.

Whenever he was sick, Washington was always downhearted, and thought that the end was at hand. Yet he never showed the least sign of fear, but always maintained that he was ready to meet death at any time.

Washington was large of stature,—six feet, three and a half inches in height,—and was athletic and muscular. He lived much in the open air, and had the reputation of eating simply. Yet he was peculiarly subject to sickness.

Dr Wells has made a valuable contribution to medical literature by rendering available the facts about the health history of George Washington.

---

## QUEENS COUNTY MEDICAL SOCIETY

The regular meeting of the Queens County Medical Society was held on Tuesday, January 25th, 1927, at 8 30 P. M., at Jamaica Lodge I. O. O. F., No. 247, 159-29 90th Avenue, corner 160th Street, Jamaica. President, Joseph S. Thomas, in the Chair. The minutes of the annual meeting, as published in the Bulletin were approved.

Dr Fleming reported for the Censors, who recommended the following physicians who were elected to membership:

Harold W. Draffin, M.D., 102 Clinton Avenue, Jamaica, L. I.

Everett Godfrey Fausel, M.D., Jamaica Hospital, Jamaica, L. I.

Max Lehman, M.D., 161 Hallock Avenue, Ridgewood.

John William Mahoney, M.D., 36-33 Bell Avenue, Bayside, L. I.

Joseph William Mooney, M.D., 2810 Ditmars Avenue, Astoria, L. I.

Adalbert Schafer, M.D., Cross Island Boulevard and 34th Avenue, Auburndale, L. I.

Margaret Stanley-Brown, M.D., 151 Quentin Street, Kew Gardens, L. I.

Ivan Snider, M.D., 3664 Sixty-fourth Street, Woodside, L. I.

Adam B. Wolf, M.D., 968 Forest Street, Ridgewood.

An informal report of the Legislative Committee was made.

Dr Thomas brought before the Society the matter of members volunteering to attend the camps of the Boy Scouts during the summer of 1927, for periods of two weeks or longer if desired.

The following scientific program was presented:

1. Paper, "Some Practical Points in the Treatment of Fractures," by H. C. Courten, M.D.

Dr Courten discussed the management of cer-

creation of a county health unit is contemplated, the movement be initiated in the Medical Society of the county, and

"That the County Medical Society manifest its cooperation by taking favorable action at its earliest opportunity, and

"It is also desirable that when the county health unit is established, the County Medical Society shall keep itself fully informed and, from time to time, submit suggestions, concerning the plans and operation of the unit, and interest itself in securing constructive cooperation between the members of the profession and the constituted legal health officers"

This resolution was unanimously adopted.

After some further discussion as to the reasons for establishing a county health officership, it was suggested that a representative from each of the two organizations and from the Department of Health, be requested to confer on the details of the creation of county health units, and report to their several committees the results of their deliberations, such committee it was suggested, should consist of Mr Nelbach from the State Charities Aid Association, Dr Lawrence from the State Medical Society, and a representative that Dr Nicoll might name from the Department of Health

### THE LAST ILLNESS OF GEORGE WASHINGTON

The *Virginia Medical Journal* for January contains an article entitled "The Last Illness, and Death, of George Washington," by Walter A. Wells, M.D., of Washington, D.C. The paper is the result of much historic research, and was read before the annual meeting of the Medical Society of Virginia, in New York on October 13, 1926. The article is of extreme interest, especially at this season of the anniversary of his birth, but space permits the publication of only the following abstract

Thursday, December 12, 1799, was raw, but Washington rode about his farm from ten until three o'clock, all through a sleet storm. On Friday, the 13th, Washington has a severe sore throat, but went out to mark some trees in the afternoon. That night he was hoarse, but he looked over the papers and read many extracts aloud. On Saturday, the 14th, he called Mrs. Washington at 3 o'clock in the morning, saying that he felt very sick and had an ague. He could then scarcely speak, and he breathed with difficulty, and could hardly swallow. At about daybreak a pint of blood was drawn from the General by the overseer of his farm.

The first call of his physician, Doctor Craik, was made at 9 o'clock that morning. The doctor bled Washington again, and gave him a gargle, which nearly strangled him. At 11 o'clock the bleeding was done for a third time. At 3 o'clock Dr. Elisha Dick, of Alexandria, and Dr. G. R. Brown of Port Tobacco, came to consult with Dr. Craik, and the three bled Washington for the fourth time. The record is that the blood came slow and thick, but there was no fainting.

All through the afternoon Washington appeared to be in great distress owing to the difficulty of breathing. He continued in that state up to ten minutes before the end, when he breathed easier. He died between ten and eleven o'clock on that Saturday evening, December 14, 1799.

The diagnosis made by the attending physicians was cyanche trachealis. Dr. Wells

suggests four possible diagnoses according to the present standards

- 1 Acute laryngitis
- 2 Quinsy
- 3 Laryngeal diphtheria
- 4 Inflammatory edema of the larynx

Dr. Wells discusses each of these possibilities, and decides that the fourth is correct. He gives the sources of information available to doctors in 1799, and says that a textbook on medicine in common use was "First Lines in the Practice of Medicine," by William Cullen, Professor of Medicine in Edinburgh, from which place both Doctor Craik and Doctor Brown graduated. Dr. Cullen describes cyanche trachealis as a rare disease, attended with a croaking voice, difficult respiration, fever, a sense of "straightening" about the larynx. "It does not always run a course of inflammation, but frequently produces such an obstruction of a passage of air as suffocates and thereby proves suddenly fatal."

Regarding treatment, Dr. Cullen's book says "As we suppose the disease to be an inflammatory affection, so we attempt a cure of it by the usual methods of inflammation and which for the most part we have found effectual. Bleeding, both topical and general, has often given almost immediate relief, and by bleeding repeatedly has entirely cured the disease. Vomiting immediately after bleeding seems to be of use, and sometimes removes the disease."

Dr. Wells discusses the two modern treatments, adrenalin and tracheotomy, which would be used today. Adrenalin was discovered in 1901 over one hundred years after Washington's death. Tracheotomy was first done in 1782 by Andree of London, but the operation was seldom used. Two French surgeons had published a pamphlet in 1798, advocating the operation in angina, but it was not generally accepted as of much value until 1826 when Bretonneau wrote on laryngeal diphtheria.

The discussion was closed by Drs Greenberg and Boas

Dr Cuniffe introduced the newly elected president who took the chair and delivered the following inaugural address

"With the advent of the new year, certain very definite problems loom up for our consideration. For the purpose of discussion these may be classified into three divisions: Scientific, Public Health, and Economic. There really is no distinct line of cleavage between the scientific and public health, and there certainly is a decided fusion of public health and economic problems.

"Only a small percentage of physicians in the City of New York have access to hospitals. It shall be our aim to enlarge the field of hospital facilities available to the general practitioners.

"It will be the aim of the Scientific Committee to present to the Society papers of general scientific interest rather than of subjects of a specialized nature. We again urge the organization of special Sections where such of our members who desire to limit their study and practice may find others similarly inclined, ready and willing to cooperate with them in their investigations and study.

"Among the Public Health problems which come to the fore are some of those which we have inherited from the previous years and which are still in the formative stage. Periodic Health Examinations of apparently healthy persons must continue to give us much thought during the current year. Be fully prepared for such examinations so that when the call comes, you do not hesitate, and the lay organizations, ready to aid you by ethical propaganda, do not turn from you and spurn your half-hearted response, and instead purchase your business-loving associate to do the work for them.

"The active immunization against diphtheria by toxin-antitoxin is a problem which we must take hold of immediately. The State Society has undertaken this campaign throughout the rural districts, while Dr Harris, the Commissioner of the New York City Department of Health, is putting forth strenuous efforts to immunize all children that can be reached through the agencies of the Department Baby Health Stations and the public schools.

"Various welfare organizations notably the New York Tuberculosis and Health Association, through their several Borough Committees, are planning to distribute cards and leaflets in this campaign of educating the public. Members of this Society should be ready. Inform your clientele of the value and importance of these injections, and immunize their children without delay.

"The Committee on Public Health and Medical Education is prepared to work in harmony with any doctor who desires to advance the general purpose of educating the people in health matters.

"It is the Economic problem, however, which

gives us most concern. It is becoming increasingly more evident daily that the opportunity for the young physician to live in accordance with the standard more nearly suited to his qualifications and scientific attainments is non-existent. Indeed, the more mature practitioner cannot frankly boast of a large measure of financial success.

"In private practice, even on superficial investigation, it becomes immediately apparent that while health is of paramount importance, the smallest item of the family budget is for medical services. This applies to the wealthy no less than to the poor. Only recently the trustees of an estate were haled to court by the guardian of a poor little rich girl, twelve years of age, to show cause why the poor orphan should not have her allowance of twelve thousand dollars increased to twenty thousand dollars annually. Among the items enumerated for her expenses, which included thousands of dollars for food, clothing, education and amusements, the entire sum available for medical services was six hundred dollars, three per cent of the annual allowance pleaded for. And this for a child of twelve whose physical well-being ought pre-eminently have first consideration.

"On the other hand, while the poor suffer from the lack of means with which to purchase proper and sufficient food, clothing, and habitation, they are the recipients of gratuitous medical services when ill. And while wonderful structures are being erected to house the sick poor, the doctor's name is seldom mentioned in connection with the institution, even though he is giving his services freely to check suffering and aid humanity.

"True, in the days of old when the physician ministered to the body as the holy man ministered to the soul, payment for services was no consideration, but we are not living in the days of the ancient Pharaohs. We are an integral part of a great struggle for supremacy, and whether we admit it or not, we shall either be vanquished and become mere commodities to the masses, or be victors and again take our place as leaders and respected men of science and benefactors of the human race.

"Why we have failed thus far and how to retrieve our former position should occupy our attention. Let us diagnose our own ills, and by intelligent endeavor and concerted effort eradicate the cause and return to a healthy economic state commensurate with the dignity of our profession.

"A well defined syndrome appears to us commonly present to explain our weakness, however complex its character may seem and no matter what its ramifications. It is the failure to work in unison, the lack of harmony in our struggles for recognition. Among laymen this discord among physicians is a by-word, and unfortunately for us, is utilized by them for our own undoing.

tain common fractures outlining methods of reduction, position in which the limb should be placed and types of retention apparatus

Special emphasis was placed on the use of the X-ray and the securing of film records of the course of the fracture, from its original condition until its final discharge

The talk was illustrated by X-rays of the various fractures mentioned

2 Paper, "Dust and Pollen-borne Diseases," by Albert Vander Veer, Jr., Deputy Physician, New York Hospital, O P D

Dr Vander Veer spoke of dust hypersensitivity, due to the ordinary dust of the house, occurring more frequently during the winter months and in children. There was often an hereditary history of hypersensitivity and the child was subject to respiratory affections, commonly mild but which might be a true bronchitis or even pneumonic. Dust sensitivity was revealed by the reaction to the intradermal test with extract of house dust. To prepare the extract, to one volume of dust from the vacuum cleaner was added two volumes of physiological salt solution containing 0.4% phenol and after sufficient contact at room temperature this was filtered through a Berkefeld filter. There should be no sterilization by heat. An amount of the extract sufficient to see was enough for the intradermal test.

The treatment of the dust hypersensitive child consisted of keeping him in a dust free atmosphere, especially in the bedrooms, from which carpets, rugs and feathers of all kinds were excluded, allowing on the floor only rugs that could be frequently washed. When the weather permitted, the child was kept out of doors. Active

immunization was accomplished by subcutaneous administration of the extract, beginning with 0.1 cc. and repeating every fifth day over a period of some weeks. When established, active immunity was maintained by the administration of one dose every month throughout the winter.

Dr Vander Veer explained that only airborne and not insect borne pollens produced pollen disease. He explained that over one-half of the hay-fever cases were hypersensitive to rag-weed (late cases), any one variety of which was sufficient for the test and treatment. One-third were hypersensitive to grasses (end of May to end of July) and responded to Timothy. Ten per cent were early cases (month of May) were mild and not very important. Pollen extract was standardized by the nitrogen content. In strong concentration, its action might be dangerous. Hence commercial preparations were made weak. These were suitable for highly sensitive cases but less valuable for less sensitive cases. They were administered subcutaneously for immunization, avoiding veins. Severe reactions were indicated by itching, giant urticaria, marked malaise, general appearance, production of asthma, etc., and were treated by stopping absorption with tourniquet around arm and administering 5 to 10 minims adrenalin. Patient should remain in office fifteen minutes after which there was no danger of severe reaction. Results of treatment, satisfactory in 85%, improvement in 10%, no improvement in 5%. Discussion by Drs E E Smith and J J Salerno.

A vote of thanks to the speakers of the evening was passed.

## BRONX COUNTY MEDICAL SOCIETY

A regular meeting of the Bronx County Medical Society, held at Concourse Plaza, on January 19, 1927, was called to order at 9 P M, the retiring President, Dr Cuniffe, in the Chair.

Dr Cuniffe thanked the members of the Society for their cooperation and expressed his appreciation of the work of the committees during the past year. He especially thanked three members of the Society, past presidents, Dr Simon M Jacobs, Chairman of the Building Committee, Dr Philip Eichler, and Dr Edward C Podvin, Chairman of The Bulletin Committee.

The following candidates were elected to membership: Raphael Bellantoni, Abraham Clahr, Charles Wilmer Fitch, Irving Friedman, Samuel Gartner, Emanuel B Kaplan, Max Kliger, Abraham D Teitelbaum.

Dr Gitlow, appointed by the President as a committee to appear at a conference at the Board of Health, at which Dr Harris presided, reported

that at that meeting the main decisions were that, first, laboratories shall be supervised and registered by the Department of Health, and, secondly, nobody shall be a director of a laboratory unless he have a medical degree, or an A B, B S, M S, Ph D or Phar D, and if he has the necessary degree, he shall also be required to present suitable evidence that he is capable of running a laboratory.

The scientific program then proceeded as follows:

1 "Some of the Early Manifestations of Coronary Disease," David Greenberg

2 "Some Modes of Infection in Rheumatic Fever," Ernest P Boas

The discussion on Dr Boas' paper was opened by Dr Murray H Bass. Discussion on Dr Greenberg's paper was opened by Dr Sydney Steiner. Others participating in the discussion were Drs Seifin, Jacobstein, Fisher and Leiner.

# THE DAILY PRESS

## FAMILY BUDGETS

How much money does it take to support a family? The newspapers have recently discussed that question from the standpoint of the opposite ends of the scale

The New York Herald-Tribune of January 28 carries an article on the amount spent by the 4,000 families who live on Park Avenue, New York, between thirty-fourth and ninety-sixth streets. The figures are given by the Park Avenue Association, Inc., which made a statistical research into the expenses of the families living in this area

The average yearly income of the families is over \$75,000—while some are over a million. This income is spent for the following purposes

	Average per Shopping day	Average per year
Amusements, Theaters, cabarets, etc.	\$19,230	\$5,000,000
Art Galleries and antiques	57,690	15,000,000
Automobiles	38,460	10,000,000
Auto renting	3,840	1,000,000
Candies	7,692	2,000,000
Charity	19,230	5,000,000
Drugs perfumes, etc.	15,384	4,000,000
Electric Appliances	7,692	2,000,000
Flowers	11,538	3,000,000
Foodstuffs	76,920	20,000,000
Furniture, decorations, rugs, etc.	57,690	15,000,000
Furs	61,536	16,000,000
Garaging	19,230	5,000,000
Gift Things	19,230	5,000,000
Glass and china	7,692	2,000,000
Hairdressing and beautifying	15,384	4,000,000
Hardware	7,692	2,000,000
Jewelry	76,920	20,000,000
Laundries and cleaners	13,461	3,500,000
Leather goods	7,692	2,000,000
Linens, laces, etc.	19,230	5,000,000
Men's shoes	7,692	2,000,000
Men's wear, tailoring, haberdashery, etc.	57,690	15,000,000
Millinery	26,922	7,000,000
Moving and storage	3,846	1,000,000
Music, pianos, etc.	9,615	2,500,000
Real estate (rentals)	69,228	18,000,000
Restaurants and Catering	38,460	10,000,000
Stationery	7,692	2,000,000
Traveling, foreign and domestic	57,590	15,000,000
Women's shoes	15,384	4,000,000
Women's wear	192,300	50,000,000
Yachts	26,922	7,000,000
Totals	\$1,096,107	\$280,000,000

The expenditures for a family near the other end of the social scale are discussed on February 13, in the New York Times. The article states —

"How much does a New York family maintaining a fair standard of living require for its needs? The question has been studied by the

National Industrial Conference Board, with the cooperation of retail stores, real estate men and business executives

"A corps of field workers under the direction of Margaret Loomis Stecker, who conducted the survey for the National Industrial Conference Board, went into rooming houses and to numerous social agencies to find out what it costs the working girl to live"

The object of the survey is stated in the following extracts

"The results, while not offered as a complete analysis of the cost of living in New York City, are held to be a fair approximation of the average minimum requirements to maintain a fair American standard of living. The conclusions are of particular interest since there has been no general study since the Federal survey of 1919. Recurrent wage negotiations furnished a need for the estimate. The effect of the migration of workers from the more densely populated districts to the outer rim of the city provided another striking reason for the study.

"What industrial workers and office workers are actually required to spend now to maintain a minimum standard has been worked out in carefully prepared tables and charts. Employers who are concerned with cost of living statistics as a basis for wage adjustments will find detailed answers to their many questions in the report.

"The Labor Bureau, Inc., using the minimum health and decency budget of the United States Department of Labor as priced to June, 1926, would set an annual total of \$2,330.93 as "a bottom level below which a family cannot go without danger of physical and moral deterioration." For the manual worker's family in Queens, the Board's estimate is \$436.17 below the Federal minimum and \$177.98 less for the office worker."

The actual budgets are discussed as follows. "The investigation shows that rents, fuel, clothing and other costs fluctuate widely in the various boroughs of New York, while the cost of living is virtually identical in all. An industrial worker's family of five requires, it is estimated, a minimum of \$1,880 a year, an office, or white collar, worker's family of the same size requires \$2,119. On this basis the factory worker must earn \$36 a week and the office worker nearly \$40. Rent continues to be the most impressive burden on the head of the family.

"A Brooklyn office worker, out of his \$40

While we may adopt various measures after proper discussion and study to ameliorate the economic status of the practicing physician, none will avail us except by a harmonious accord among us.

"A plan entirely suitable for our purposes, to which I have given considerable thought, I now desire to present to you for your earnest consideration. It represents a scale of fees for medical services rendered by the general practitioner in his private practice.

"We are well aware that the prevailing system of receiving remuneration at so much per call, generally three dollars for a home visit and two dollars for an office consultation, is erroneous, lacking in justice to the physician and fairness to the patient. To give such attention to a case as may be found essential for its successful treatment, a physician should not be limited in the number of calls to the bedside because of his desire to retain cordial relations with his clientele by reducing the amount of his bill to a minimum, on the one hand, nor, on the other, are we so entrenched financially that we are willing to make

numerous calls gratis, just so that our professional conscience may remain undisturbed.

"A retainer charge, if you please, of a minimum of ten dollars for an outside call for the purpose of diagnosis and treatment of a simple condition such as an acute tonsillitis, which may or may not require one or two additional visits for which no additional charge be made, should be the accepted rule. If a diagnosis be made of a disease of more or less limited duration, such as the more common infectious or communicable diseases, a definite fee be charged at the outset, such as fifty dollars for scarlet fever, twenty five dollars for diphtheria, fifteen dollars for measles, and with the provision that in the event of complications or sequelae other additional charges in proportion be allowed.

"Such a procedure will put a case completely into the hands of the practitioner who with the sense of security that his calls are not limited by the fear of antagonizing the family, will in fact gain its approval and complete confidence by his earnest attention to the care of his patient."

### SCHUYLER COUNTY MEDICAL SOCIETY

The annual Spring meeting of the Schuyler County Medical Society was held at The Glen Springs, Watkins Glen, New York, on June 10, 1926, president Rollin O. Baker occupying the chair, and a quorum being present. Dr. George H. King was elected president, Dr. John M. Quirk, treasurer, and Dr. Frederick B. Bond, secretary, for the ensuing year.

Dr. Albert Warren Ferris was elected delegate to the 1927 meeting of the State Society,

and Dr. Rollin O. Baker, alternate delegate.

Dr. John R. Williams, chief of the Medical staff of Highland Hospital, Rochester, read the paper of the evening, on "Hypertension Under the Use of Liver Extract."

Fifteen Physicians from neighboring towns were present, together with their ladies, all of whom were entertained at dinner, before the meeting, by the Management of The Glen Springs.

### OTSEGO COUNTY MEDICAL SOCIETY

The Annual Meeting of the Otsego County Medical Society was held in the Oneonta Hotel, December 14, 1926, with Dr. R. W. Ford in the chair, Dr. J. C. Smith recording, and twenty members present.

The nominating committee reported on the following names and on vote the secretary cast a ballot for their election. President, Dr. F. H. Marx, of Oneonta, Vice-President, Dr. F. J. Atwell, of Cooperstown, Treasurer, Dr. F. L. Winsor of Laurens, Secretary, Dr. A. H. Brownell, of Oneonta, Censor, Dr. J. W. Swanson, of Springfield Center, Delegate to State meeting, Dr. A. H. Bissell of Cooperstown, Alternate, Dr. L. C. Warren of Franklin.

Dr. Mills made a report on County Laboratory

foundation. After some discussion the matter was left with the same committee for further consideration.

The matter of display diphtheria immunization cards in the waiting room of the physicians was approved.

The Secretary was requested to write Dr. Gordon of Brooklyn to arrange a series of lectures for the Society beginning any time after the middle of March.

Dr. Marx presented a new treatment of varicose veins.

After dinner Dr. John E. Jennings gave an illustrated lecture on "Cancer of the Breast" that was full of interest and information for the members.

### DR. JAMES B. CROFF

Dr. James B. Croff, Secretary of the Erie County Medical Society, died suddenly and alone on January 31, in his office in Buffalo. He was

well known and respected, and took a deep interest in his County Medical Society and in civic medicine.

# BOOK REVIEWS

**METHODS AND PROBLEMS OF MEDICAL EDUCATION** Fifth Series Division of Medical Education, The Rockefeller Foundation, New York City, 1926 Quarto of 225 pages

This is the fifth in the series of collected teaching methods published by the Division of Medical Education of the Rockefeller Foundation. Although mostly given over to Washington University and McGill, clinics and departments of other medical schools are included. There is a very interesting description of the Didactiscope, an ingenious reflecting device for witnessing operations and a unique clinical record chart from Mount Sinai Hospital.

C. A. G.

**OBSTETRICS** By John S. Fairbairn, M.D. 16mo of 221 pages, with 29 illustrations. London and New York, Oxford University Press, 1926. Cloth, \$1.75 (Oxford Medical Publications).

Fairbairn's little handbook surveys the entire field of obstetrics in a brief yet very comprehensive way. There is not a line of padding in the book. Not just a short text book—or anything like a compend—it is an excellent example of what a text book for the medical student might very well be. The perspective is excellent and detail, though limited, is sufficient. A very creditable and useful book.

C. A. G.

**THE ABDOMEN IN LABOUR.** Being a General Practitioner's Clinical Study of the Parturient Abdomen. By Norman Porritt, M.R.C.S., L.R.C.P. (Lond.) 12mo.

This little book is unique in that it represents the accumulated observations of a general practitioner in a life long clinical study of the parturient abdomen. Much that he discovered for himself is not new, yet his sketches of fetal positions are very interesting. The book severely criticises the left obstetric position so popular in England, and makes a very convincing argument for the dorsal. Would that all general practitioners had the clinical instinct so well developed.

C. A. G.

**GENIUS** Some Revaluations. By Arthur C. Jacobson, M.D. Octavo of 160 pages. New York, (Adelphi Company) Greenberg, (1926) Cloth, \$2.50.

It is eminently fitting that this book should be written by a physician, since the critical study of genius in its biological relationships belongs properly to medicine, and it is fortunate for the reader that a physician with such rare qualifications for the task, literary and otherwise, as Dr. Jacobson, should have done it. It is difficult to review the book in limited space because it is so full of interesting things. We can only allude to a few of the topics discussed in it, as

The relationship of the divided consciousness, the secondary personality, to creative activity. The cases of many geniuses are cited to show how dependant on release from inhibitory mechanisms by various agencies was their creative activity.

The special part played by alcohol in freeing genius from its inhibitions.

Certain pathological relationships of genius, and the disastrous results of the intoxicating and narcotic drugs used by the possessors of genius to release it from its inhibitions, and also the destructive effects of the disease toxins which produced the same release in so many cases. It is pointed out how these possessors of genius sacrificed themselves for their creations, and how the

world too often ignored the debt which it owed to them, and treated them with indifference and inhumanity. Which reminds us of what Goethe said of the world's treatment of its geniuses: "Some they stoned and some they crucified."

The relation of tuberculosis to the creative mind. The cases of fifty odd literary stars of the first magnitude are analyzed with special reference to the part played by tuberculosis in their literary productiveness.

The alleged "insanity of genius," which the author denies. A most interesting critical study of the case of Swift is given, and the sanity of that great genius vindicated.

The relationship between double or multiple personality and ethnic hybridism. The cases of Presidents Wilson and Roosevelt are compared. The former, of fairly pure ethnic strain, did not reveal "incongruous traits assignable to different personalities," while the latter, in whom a number of different ethnic strains mingled, was a "bundle of contradictions." The author cites many cases illustrative of the good and bad effects of ethnic hybridism, but says that "the possession of a multiple personality spells neuroses and psychoses more often than it spells Roosevelt."

The part played by a "bad" ancestry in the development of genius. The author concludes that from the viewpoint of the development of genius such an ancestry is not always to be deplored. He cites the case of Jonathan Edwards, whose paternal grandmother was divorced for adultery and other immoralities, and expresses the opinion that the energy and well known vigor and will to freedom of this grandmother "constituted biologically considered, an excellent inheritance."

The scientific merit of this book, its wealth of literary allusions, its intense human interest and its singular charm of style, give it a wide appeal—to the philosopher, physician, biologist, psychologist, sociologist, litterateur, artist and man of culture generally, and also to the "intellectual plebeians," to use the author's phrase, whose lower curiosity relishes intimate details about those with shining names. The fact that there are many things in this book which will shock and even antagonize some people will not detract from its interest.

EDWARD E. CORNWALL.

**OBESITY** By LEONARD WILLIAMS, M.D. Octavo of 171 pages, with 20 illustrations. London and New York, Oxford University Press, 1926. Cloth, \$3.35 (Oxford Medical Publications.)

The author feels that a treatise on Obesity should appear at frequent intervals and indicate the current attitude towards this condition. He writes, "The unlovely condition called corpulence, or obesity, has been divided into three stages, known respectively as the enviable, the comical, and the pitiable. Such a classification is based upon a false estimate of values, for no case of obesity is enviable, most of them are, in a sense, comical, and all are pitiable. There are only two kinds of obesity—the one is alimentary in origin, and is caused by surfeit, the other is endocrine in origin, and is caused by under-action of an endocrine gland." The author, in this volume of 170 pages, shows the ill effects of overeating and insufficient exercise. The second part of his task is to show the evil effects of abnormal action of some of the endocrine glands, this is a speculative field to date. The book has been carefully prepared, is well written and instructive.

H. M. MOSES

expense every week, must give \$10 to the landlord, nearly \$15 to the grocer, butcher and milkman, and spend at least \$5 to clothe himself, his wife and three children, while more than \$9 goes for sundries, including candy, tobacco, insurance, recreation and the like. The same sized family in Manhattan would cost \$41.47 to maintain.

"A factory worker who lives in Queens, to provide for his wife and children, splits his \$36 weekly minimum expense into \$7.38 for the landlord, twice as much for food, nearly \$5 for clothing, and about \$8 for sundries. In addition, he must pay for coal, which brings his housing cost to the same level as that of the Brooklyn office worker.

"The following yearly estimates are for Queens

	Manual Worker's Family	Office Worker's Family
Housing	\$384.00	\$480.00
Fuel, light	87.50	107.80
Food	762.32	762.32
Clothing	248.62	290.63
Sundries	411.32	512.20
Total	\$1,893.75	\$2,152.95

"Although the cost of living was practically identical in all boroughs, the differences in certain expenses were rather striking. For the families of industrial workers there was a very slight financial advantage to be gained by living in Brooklyn, with Richmond, Queens, the Bronx and Manhattan a little higher in the order named. The average for the city as a whole differed from the average for the separate boroughs by less than \$1 a week.

"Although generally his salary lags behind the wages of the mechanic and factory worker, the office worker's expenses were found to be uniformly heavier. He lives in a better house and he has to dress better to hold his job. Not only the kind of clothing but the length of time it may be worn is different from the white collar worker than the factory toiler. His children do not live in an industrial community and therefore have to be better clad. He has to pay more rent than the mechanic who wants to live near the shipyard, refinery or factory where he is employed. Nor can the office worker as a rule take his lunch to the office, he cannot eat as coarse meals and the cost of what he gets is higher."

Comment on these two sets of budgets belongs to statisticians and moralists rather than physicians.

## ANTI-EVOLUTION LAWS

The New York *Tribune* of January 10 records the passage of an anti-evolution bill by the lower house of the Arkansas Legislature, and the defeat of a similar bill in New Hampshire where it died in committee.

Bills forbidding the teaching of human evolution in public schools are pending in about a dozen states. Their supporters justify them on religious grounds, fearing that evolution is opposed to current religious creeds that are founded on the Bible, and is especially at variance with the story of the origin of man as told in the Bible. This JOURNAL during the past year has printed comments of leading scientists regarding what is known of the antiquity of man and his origin. (See this JOURNAL, March 15, 1926, page 290, August 1, page 691, and October 15, page 877.)

What has this agitation over evolution to do with physicians? One application is that a renowned champion of the literalness of the Bible, Dr. John Roach Straton of the Calvary Baptist Church, New York City, is quoted by the New York *Herald-Tribune* of February 7 as saying:

"There is still undoubtedly a place for the

doctor in the scheme of human life, especially in the field of diagnosis, prevention, and the simpler forms of surgery. Doctors and drugs are for helping through Nature, and for the natural man and those who do not know the truth. Divine healing is for those who fully trust the Lord and have the faith to walk with Him without any human crutch or dependence whatsoever. The Hebrews throughout their journeyings through the wilderness had no doctors and no drugs. The secular schools of scientific medicine do not make even an effort to get at the root of disease, namely, sin."

Dr. Straton was also quoted as saying that he had come at last to stand with those who are opposed to vaccination of helpless children.

Dr. Straton is representative of the group that consider the Bible to be as literally true in science as in revelation. In contrast with his attitude is that of Dr. Harry Emerson Fosdick whose address on "The Debt of Religion to Science" is printed on page 173 of the February 15 issue of this JOURNAL.

WHEN symptoms of insufficient nourishment make their appearance, the routine use of

**DRYCO**

usually leads to a prompt return of the baby's weight to normal

In the majority of cases, the infant deprived of breast milk adapts itself to Dryco without difficulties, at the same time showing a marked gain in weight

Dryco furnishes a nutritious food, free from pathogenic bacteria and in a condition for complete absorption and assimilation

## RURAL MEDICAL AND HOSPITAL SERVICES

*Extracts from a paper by Dr W S Rankin, Director Duke Endowment, Charlotte, N C, published in the American Journal of Public Health, January, 1927*

The predominant interest of public health has moved farther and farther away from environment and nearer and nearer to man himself. Having cleaned up his surroundings, having cut the trunk lines of morbid communication, having closed practically all avenues of infection except the unsuspected and undetected carrier, public health within recent years has sought to protect where it could not prevent. Prevention is public, protection is personal. So today, especially in the more advanced health departments, we find an increasingly larger part of the budget going into pre-natal clinics, infant welfare clinics, medical inspection of schools, and periodic health examinations.

The future of public health will be determined by the medical services of the country—by their adequacy and their availability.

**Personnel and Facilities**—In considering the adequacy and availability of the medical services of this country, let us be sure that we have the same understanding as to what the term is intended to include. Medical services as here used consist of two parts: (1) medical personnel, and (2) medical facilities or hospitals. Medical personnel and medical facilities are so closely related that we get a wholly distorted picture if we look at the one without the other. Adequate facilities—a good hospital service, with the assistance of nurses and technicians—enables one doctor under urban conditions to do the work of at least two doctors without such assistance. And under rural conditions, where spaces are great and time consumed in travel commensurate, adequate facilities will enable one doctor, with his patients brought to him and with the assistance of nurses and technicians, to do the work of not less than three or four doctors without such supplementary services. With medical facilities restricted or absent, a large medical personnel is necessary, with facilities provided and adequate, a small medical personnel can meet the needs.

**Adequacy of Medical Services**—From time to time it is charged that the medical services of this country are inadequate. These charges rest largely upon a decrease in the number of medical schools since 1906 and an increase in population. The proportion of physicians to population fell off but 15 per cent, from one physician for 670 people, to one for 772 people, an addition to the average practice of 102 people. Along with this slight decline in medical personnel in proportion to population there occurred a tremendous increase, more than 100 per cent, in medical facilities

or general hospital beds. Keeping in mind the fact that facilities double and treble the service arm, the reaching power of the doctor, and that medical services include *both* personnel and facilities, we are safe in saying that medical services have not been decreased, either absolutely or relatively, since the change in the order of medical education and practice (usually regarded as effected in 1906). On the contrary, medical services have been greatly augmented. With one doctor for every 772 people, and with 25 general hospital beds for every 1,000 population there is no inadequacy of medical services in this country about which to become alarmed. There are other phases of the medical problem far more deserving of our concern.

**Availability of Medical Services**—Medical services may be adequate but not so distributed or placed as to be physically and financially accessible to a large proportion of the population.

With respect to medical personnel, for the year 1923, in towns of 1,000 population and under, there was one doctor for 1,238 people, in cities of 100,000 population and over, there was one doctor for 536 people, or, in other words, the medical personnel serving urban people was twice that serving rural people. In places of intermediate population groups there was a corresponding intermediate proportion of doctors to people.

The disproportionate medical personnel is not wholly quantitative, it is also qualitative. The doctors of urban communities are, as a rule (to which there are notable exceptions, of course), the best doctors. The urban population is at least four times better served than the rural population with scientific medical care.

**Availability of Facilities**—Taking into consideration the fact that the city has twice the medical personnel and, man for man, twice as efficient medical personnel as the country, and that the city has from three to four times the medical facilities of the country, it is most conservative to say that the rural medical services of the United States are considerably less than one-fifth as adequate as urban medical services.

**Advantages and Economy of Efficient Rural Medical Facilities**—Rural hospitals or improved rural medical facilities will do three things in the building up of an efficient rural medical service.

First, they will make it possible for the best men now located in the smaller towns and cities to enlarge their field of service, (1) by supplying these men with the same nursing and technical

(Continued on page 268, *adv xvi*)

## SKIN TESTS IN BRONCHIAL ASTHMA

The February issue of the *Atlantic Medical Journal*, the official organ of the medical societies of Pennsylvania and Delaware, contains an article on "The Interpretation of Skin Tests in the Diagnosis of Bronchial Asthma" by Dr. Richard A. Kern, of Philadelphia, Pa. The following extracts from his article describe some of the observed discrepancies between the manifestations of protein sensitiveness in the bronchi and those in the skin—EDITOR'S NOTE.

When the allergic nature of certain diseases—asthma, hay fever, vasomotor rhinitis, some types of eczema, and others—became recognized a few years ago, skin testing was hailed as a valuable addition to our diagnostic armamentarium, and such it has indeed proved to be. However, many discrepancies have been found between the skin reactions, on the one hand, and the clinical picture and therapeutic results on the other, discrepancies which have led the unskilled into error and which have shaken the faith of many in the value of the method. The proper interpretation of skin tests and their limitations are the subject of this discussion. Skin reactivity does not parallel either the intensity or the type of the clinical picture presented by the patient. Skin hypersensitiveness is one manifestation of general hypersensitiveness. Fortunately for us, it usually accompanies hypersensitiveness of other parts of the body, for instance the nasal or bronchial mucosa, but it may be greater or less in degree, or perhaps, wholly absent, or it may be present alone, without clinical manifestations of hypersensitiveness elsewhere. These various combinations give rise to obvious difficulties.

Skin reactivity is not proportional to the severity of the clinical picture. Of two asthmatics, both sensitive to horsehair, the one may give a very markedly positive skin reaction to horsehair protein, while the other reacts only very slightly. Therefore, we cannot judge the severity of the disease by the result of the skin test. What is more important, it makes it more difficult to decide what to call a positive reaction.

Another type of reaction that may easily be overlooked is the delayed positive. These are apparently very rare, but the writer has met one undoubted example. A patient with angioneurotic edema on several occasions by both cutaneous and intracutaneous testing with onion protein gave a reaction that never appeared in less than two or three hours, and which would increase for as long as twenty-four hours when the material was injected into the skin. If he ate onions, he would invariably have a severe outbreak of urticaria to the point of frank purpuric lesions.

Is skin sensitization ever completely absent in the presence of hypersensitiveness elsewhere in the body? I believe that this does occur. Va-

(Continued on page 270—Adv XVII)

OLD FRIENDS  
ARE BEST

**T**IME provides the acid test for many things. Acquaintance grows into respect and respect into friendship as the years pass and positive qualities have an opportunity to assert themselves. It is thus with human friendships, and we see a marked parallel in the relation of the physician to the drugs upon which he relies.

New and untried remedies come and go. Many enjoy a brief moment of popularity. Few survive the acid test of time.

Creosote is still a favorite drug for use in the treatment of bronchitis, tuberculosis, and as an intestinal and urinary antiseptic. Its expectorant and antiseptic properties are generally recognized and the discovery of Calcreose more than a score of years ago has largely overcome its principal defect, which was the tendency to cause gastric disturbance.

The Maltbie Chemical Co. of Newark, N. J., contributed a distinct improvement to the *Materia Medica* of our time when it made Calcreose available as a therapeutic agent. By combining a high quality of creosote with hydrated calcium oxide we have been able to prepare a compound of creosote which breaks up rapidly in the intestinal tract, releasing the creosote for therapeutic purposes and avoiding the usual disturbance experienced when plain creosote is used.

Another advantage of Calcreose over plain creosote is that it is a powder and can be manufactured into tablets, thus facilitating the administration of this valuable drug.

We are always glad to supply samples of Calcreose Tablets to physicians for their personal use or for the purpose of testing its value upon their patients.

# Cod Liver Oil

for

## Every Baby

It is now quite the common practice among physicians to prescribe cod liver oil for all babies as a protective measure against rickets or mal-nutrition

As it is advisable to start with a very small dose, it is important to know that the oil employed is of definitely known vitamin potency. Only a cod liver oil of guaranteed vitamin potency, which has been biologically tested can be depended upon to give the desired protection

In the manufacture of PATCH'S FLAVORED COD LIVER OIL, every step of the process is carefully controlled, insuring an oil which is very potent and pleasant to the taste. Each lot of oil produced in our plants is biologically tested, for your protection

If you can prescribe a small dose of pleasant tasting oil,—that's half the battle. Your patients, young and old, will appreciate such a product

Let us send you a sample so that you may taste it and be convinced

## The E. L. Patch Co.

Boston, Mass.

(Continued from page 266)

cal assistance that is available to the medical personnel of urban centers, and, (2) by assembling the patients and so saving the time of these better types of rural physicians which would otherwise be consumed in country travel. By such assistance plus such saving of time it would be possible for one first-class rural practitioner to give from two to four times the service that is possible without hospital facilities

Second, improved rural medical facilities will attract more first-class medical men to rural practices and, in so doing, relieve an urban medical congestion that had engendered a spirit of commercialism in medicine, and also relieve a rural depletion of medical personnel that has aroused public concern which has threatened reactionary legislation

Third, rural hospitals will not only afford a more efficient medical service, measured by modern standards, but will supply a far more economical medical service than is at present available to rural communities

One good doctor plus a hospital is equal to not less than three good doctors minus a hospital. An average county of 30,000 people, let us say, is served by 20 doctors, the average income of the twenty doctors, that is, the cost to the community per doctor is \$5,000. A county is far better supplied with medical services with one hospital plus twelve doctors, than without one hospital plus the twenty doctors. In added medical facilities and subtracted medical personnel we would have an improved medical service with the saving of the cost of eight doctors at \$5,000 each, an annual saving of \$40,000. This would more than pay the cost of the hospital to the public for both construction and the treatment of one-third of the patients as charity cases

The public economy of the rural hospitals appears when we consider (1) the saving of medical mileage fees to rural residents, and (2) the saving in the number of doctors necessary for rural practice. Ordinarily a mileage fee of seventy-five cents is charged for travel beyond the town or city limits. For a rural resident living from six to ten miles in the country, this means a mileage fee for each visit of from \$4.50 to \$7.50—a sum more than sufficient to pay the hospital charges, including in most cases nursing service and drugs, and a treatment given in the hospital will be from two to three times more efficient than that which is possible in the home

Provide rural hospitals and establish that magnetic influence in rural medicine that has attracted the larger and better part of the professional care and the congestion of urban cultures with medical personnel. Provide rural hospital and establish that vitalizing influence in medicine without which scientific medicine becomes sluggish, incapacitated, inert, dead

## HEALTH RESOLUTIONS

The Texas State Journal of Medicine for February prints the following health resolutions for laymen which have been promulgated by the State Board of Health —

"I shall have a complete physical examination made by my family physician at the earliest opportunity to determine if any defects exist which, if corrected now, would prevent serious organic trouble in later life

"I shall give my children protection from diphtheria by having my family physician make them immune to this disease by administering toxin-antitoxin

"I shall safeguard the health of my family and community from smallpox by the only known method to prevent this disease—that of vaccination

"I shall do everything possible to prevent the spread of communicable diseases by not unnecessarily exposing my children to infection from others who are victims of diseases termed 'catching,' and by keeping them from school when suffering with suspicious colds, or running temperature, that they may not be a source of infection to others

"I shall promote birth registration in my community by being certain that my children are properly registered with the vital statistics department of the State Board of Health, and by ascertaining if the physicians of my community are promptly registering all local births

"I shall give my city and county health officials every assistance possible in making my home community one of the most healthful spots in the state

"I shall drive my car in a manner that will not endanger my own life or the lives of others"

*The Journal comments as follows*

"While we are making resolutions for the New Year and while we are discussing the matter of New Year's resolutions with our friends and patients, why not consider the problem of health? It would require very little effort on our part to induce a large number of our patrons to think in terms of good health throughout the year and therefore resolve in terms of good health at this time of the year. Of course, we would lose somewhat by the lessened amount of illness in our clientele, but in the long run there would be no actual economic loss, for the reason, very largely, that our people would be better able to pay us better prices for what we do for them and we would have more time in which to prepare ourselves for the service we are to be called upon to render, for which we are to be paid in proportion"

# "Labor= Bundle"

Contains sterile gown, gloves, towels, leggings, cotton, gauze umbilical tape, cord dressings vulva pads, hand brush, orangewood stick and table cover

Your maternity equipment is either sterile or it is not. **THERE ARE NO DEGREES OF STERILITY**

THE 'LABOR BUNDLE' IS PACKED SEALED AND STERILIZED (after closure) IN METAL PACKAGES (heavy soldered tin) Its aseptic integrity is assured.

Without obligation on your part write the name and address of your patient on your prescription blank and mail it to us. We will send the "LABOR BUNDLE" direct to your patient C. O. D. \$5.00 postage paid. Keep a 'LABOR BUNDLE' in your office or car ready for any emergency. Your druggist will carry it for you. (The package is designed for a single use.)

rious observers have seen cases of typical seasonal hay fever or combined hay fever and asthma, yet with negative skin reactions by all methods of testing. Occasionally such a patient will give a weakly positive conjunctival or intranasal reaction to a pollen extract, pointing to a true polinosis in these individuals.

Skin reactivity may be so excessive as to be very confusing. This occurs in those individuals with dermatographia, in whom the slightest trauma to the skin causes a marked angioneurotic local swelling. In these patients, the reading of tests by the intracutaneous method is particularly difficult, for the control as well as all the tests may give characteristic wheals with irregular "pseudo-pod" outlines and a wide zone of erythema.

Skin reactivity is often present when there is no clinical manifestation due to the substances reacting positively. It is a common experience in testing an asthmatic to obtain positive reactions to one or more foods, yet eating or abstaining from these foods may have no influence on the patient's symptoms. This is probably explained in this way. Skin tests with foods do not duplicate what happens clinically. In the test a native unsplit protein is artificially brought in direct contact with cells and serum, and if sensitization to that protein exists, a positive reaction will occur. But, practically, conditions are quite different; many of our foods are first much altered by cooking, they are then probably rendered harmless by the processes of digestion, and they come in contact with an unbroken mucous membrane.

Variability in skin reactivity is not merely an individual one. Age also seems to play a part, and younger patients react more strongly than do those of more advanced years. This may account in part for the greater number of diagnostic failures in the latter. Occasionally, we find that a patient may react to a given substance in a variable degree on different days. A weakly or a questionably reacting protein may on second testing give a definite positive. Therefore, slight or questionable reactions should always be repeated.

It is obvious that skin tests have very definite limitations. Far from giving us a true picture of the etiology in a given case, they might be said to show us a much distorted image in an imperfect mirror with many flaws and not a few blind spots. To interpret the reactions properly, we must have a full realization of their shortcomings; least we fall into frequent error. Yet with all their deficiencies, the fact remains that skin tests constitute our most valuable single aid in diagnosis of human hypersensitiveness.

## RABIES IN THE VICINITY OF NEW YORK CITY

Rabies has been prevalent in the vicinity of New York City, especially in White Plains, in Nassau County, and in several parts of New Jersey. The *Journal of the Medical Society of New Jersey*, for February, contains the following article by J. Mulcady, Chief, Bureau of Bacteriology, New Jersey State Department of Health.

"During the year ending June 30, 1926, the laboratory records show that rabies has occurred in twenty of the twenty-one counties of the state. Those centrally located are most affected at the present time, Mercer County showing 39 rabid animals, Camden, 22, Burlington 19, Middlesex, 24, and Monmouth, 25, the remainder being distributed through the other 15 counties.

"Since May, 1926, all mail reports supplementing telegraphic reports sent out from the laboratory have included a request for information concerning persons bitten. Responses show that there have been victims of rabid dogs in 15 different counties of the state—a figure sufficiently impressive to prove that whatever legislation is urged for the control of this disease is in the interest of public protection.

"During a period of three years prior to 1926, ten deaths from rabies occurred in persons bitten by rabid dogs. Since March, 1926, seven persons have died from this cause, four of these despite the fact that the Pasteur treatment was given. In one of these four cases there was a delay of nine days before the treatment was started, and

death occurred before it was finished, but in the remaining three the course of injections had been completed.

"It is not possible to determine accurately the number of persons bitten during the year by rabid dogs, as bites from dogs are not reportable in this state. From information at hand, it seems certain that practically all of the 202 animals found rabid by the State Laboratory had infected from one to six persons. Therefore, a conservative estimate of the number of persons obliged to undergo Pasteur treatment as the result of bites from rabid dogs in this state would be between 400 and 500. The same rabid dogs transmit the infection to other dogs and often to valuable livestock, which in turn become new foci of infection and a continued menace to individuals with whom they come in contact. It seems only reasonable to observe that if a situation causing even a fraction of the damage done by rabid dogs was occasioned by any so-called wild animal at large in the state, effective means would be at hand to cope with this condition."

Three methods of controlling rabies are in common use (1) Muzzling all dogs running at large, (2) Destruction of stray dogs, (3) Preventive inoculations with anti-rabic vaccine.

Of all these, that of destruction of homeless stray dogs is considered to be the most effective. The inoculations are also efficient but the difficulty is to get it given to the stray dogs. The owner of a pet dog can protect his animal with the inoculations; the stray dogs ought to be destroyed on grounds of general sanitation.

# DR. BRUSH'S Kumyss

Reg U S Pat. Off

It Is Sometimes Asked  
What Is Dr. Brush's Kumyss?

Dr Brush's Kumyss is made from pure cow's milk which has been caused to undergo a vinous fermentation thereby adding three new elements, alcohol carbonic and lactic acids. It is delightfully effervescent, with a pleasant acid flavor, thirst quenching, healthful nourishing and easily digested. Dr Brush's Kumyss is never lumpy, all lumpy Kumyss should be avoided as unwholesome.

Introduced by E. F. Brush, M D, in 1876, as Dr Brush's Kumyss, it immediately won the endorsement of the medical profession. Ever since, it has been recommended by them in all forms of digestive and intestinal troubles, anemia, wasting diseases, old age and all forms of weakness.

Do not confuse Dr Brush's Kumyss with buttermilk or any milk preparation which is thick and unpleasant to the taste.

Samples without charge on receipt of request.

Superintendent

## ROENTGENOLOGIST WANTED

Applications received at Room 1400, Municipal Building, Manhattan, until 4 p m, March 22nd

Subjects: Experience Technical examination, Practical test and Citizenship. The Technical examination will consist of a paper on Roentgenology and a paper on Medicine, Surgery and Pathology applied to Roentgen diagnosis. The Practical test will consist of interpretation of Roentgenograms and Roentgen examinations and administration of X ray.

Duties: To take responsible charge of the X ray Department of Bellevue Hospital.

Requirements: Candidates must be licensed to practice medicine in the State of New York and must have served as Internue for at least one year, in a hospital of recognized standing. They must also present evidence of five years practice of medicine at least three years of which must have been spent in active work in making and interpreting Roentgenograms, and giving X ray treatment, of a character to fit them for the duties of the position.

SALARY \$3,500 per annum

One vacancy in Bellevue & Allied Hospitals

MUNICIPAL CIVIL SERVICE COMMISSION, Abraham Kaplan, President Ferdinand Q Morton and William Drennan, Commissioners Martin A. Healy, Secretary

## Wonderful Chance for Good Doctor

Young or Middle-aged Catholic preferred, very unusual opportunity, Doctor in best section of Flatbush, now going to specialize, will sacrifice practice, and corner property, double garage on 40 x 100 foot plot for price of property. Net income for several years \$35,000.00 per year. About \$15,000.00 cash required. NO BROKERS

JOHN J FITZGERALD  
1710 E. 13th STREET, BROOKLYN, N Y

## MURRAY HILL SANITARIUM

This Sanitarium is centrally located in New York City. Has a modern and fully equipped plant for Surgical and Medical Patients. All rooms are light, many with private baths, suites, if desired.

For further particulars, see their announcement on page 11

—Adv

## CLASSIFIED ADVERTISEMENTS

Classified ads. are payable in advance. To avoid delay in publishing, remit with order. Price for 40 words or less, 1 insertion \$1 50, three cents each for additional words.

WANTED—Salaried appointments for Clinicians in all branches of the medical profession. Let us put you in touch with the best man for your opening. Our nationwide connections enable us to give superior service. Aznoe's National Physicians' Exchange, North Michigan, Chicago. Est. 1895. Member the Chicago Association of Commerce.

WANTED A physician in each city of New York State to act as exclusive agent for sale of Dr Brush's Kumyss to druggists and hospitals. A liberal commission will be paid. Address Dr Brush's Kumyss Laboratory, 311 South 6 Ave., Mt. Vernon, N Y.

## PRIVATE HOSPITAL FOR SALE

A place where people don't mind being ill. 14 acres of lawn bordering stream. Fine trees and shrubbery. Beautiful location. 20 beds and nurses' quarters. Fine operating room thoroughly modern. Large home like living rooms and verandas for convalescents. 9 room bungalow for nurses. Garage and stable. Now doing profitable local business. Price \$35,000—fine because of health. Price \$35,000—terms liberal. Equipment can be bought cheap.

BATTIN & APPLEGATE

12 Broad St.

Red Bank, N. J.

WANTED—Doctor, splendid location, two churches, high school, good state roads, prosperous community that needs a doctor at once. For information write Wm. Loebeck, Snr. Borden's Condensary, North Lawrence, New York.

WOMAN PHYSICIAN—Bellevue Graduate. Desires part time work. Social Service, Industrial Compensation and Insurance Examinations. General practitioner, good all around experience. Location Greater New York only.

Write Box No. 75,

## HEALTH EDUCATION

Health education of the people by means of public schools and health officers is discussed by the February issue of the *Journal of the Medical Society of New Jersey* in an article by C E Turner of the Massachusetts Institute of Technology, from which the following extracts are taken—EDITOR'S NOTE

"It will be a great day for the public health when the people of this country generally appreciate that public health administration is not politics, is not plumbing, and is not clinical medicine

"Popular health instruction may be of three types (1) personal or direct, from the health officer, the public health nurse or the public health clinic, (2) opportune newspaper statements and every other form of scientifically prepared health literature which is placed in the hands of the citizen at a time when his situation makes him directly interested, (3) broadcasting, by means of pamphlets, bulletins, motion pictures and radio talks

"In the health education program the teacher bears the major part of the training, but the various health specialists in the school system all contribute to building into the child's personality the proper habits, attitudes and knowledge

"In first four grades the child is trained to develop health practices, the scientific reasons for which must remain unknown. From fifth grade on, organized health knowledge is provided to supplement more important training program. In eighth grade, when pupil is beginning to study civics he learns problems of community health, in ninth grade he

## ATROPHIC RHINITIS!

As a method of cleansing the nasal passages by production of Hyperemia—the

**NICHOLS NASAL SYPHON**

is very efficient

Thus writes one prominent otolaryngologist, who has now had ample opportunity to prescribe the syphon in several cases

The action is simple and sane, and the principle of syphonage is well recognized as considerable improvement over former crude and unscientific methods, which might be actually harmful in the hands of the inexperienced laity

Acts by Suction

Write today for our new booklet just printed titled "Irrigation and Drainage in Nasal Therapy" This is a very valuable book, and is replete with useful information, recommendations, etc. It contains much information for both the general practitioner and Rhinologist. It is supplied without cost or obligation

is given elementary physiology, and in senior high school basic sciences contribute further to his health knowledge

"The new and valuable element of the school program lies in its emphasis upon the health practices of the child while he is in the habit forming stage. The department of superintendence of the National Education Association in its fourth Yearbook, states that an adequate health program in the modern school system consists of three types of activities: health services, physical education and health education

"What can the health officer do to advance this educational movement? First he will familiarize himself with health education and the whole health program. Second, he will see to it that the children in the grades that are studying community health are invited to send a deputation to the Health Department to see how it is run. He will arrange the basis of departmental relationship in such a way that the School Department and Health Department are friendly and cooperative, and he will then be in a position to help the School Department in planning its health education program. The health officer should accumulate a complete set of health education source material at the Health Department, and make it easy for this material to get into the hands of teachers. The school teachers should be put on the mailing list for news letters, bulletins and other materials which they will interpret to the coming citizens

"Here is a new and important field of public health with which every health officer should have some familiarity and in which most health officers can exert a beneficial leadership"

## THE MEDICAL STUDENT AND HIS RELATION TO THE CANCER PROBLEM\*

By BURTON T SIMPSON, M D,

Director State Institute for the Study of Malignant Disease Buffalo N Y

### INTRODUCTION

ONE of the outstanding problems in medicine today is the cancer question. There is widespread interest throughout the entire civilized world in regard to this subject. Each country has one or more institutions for the scientific investigation of this disease and societies for the education of the laity in regard to the prevention of cancer, are numerous.

What is the cause of this widespread interest? Briefly, (1) statistics seem to show that cancer is on the increase and (2) therapeutic relief for cancer has not kept pace with other advancements in medical science.

It is estimated that there are approximately 120,000 deaths from cancer each year, in the United States and that there are nearly 300,000 persons suffering from this disease. In New York state, cancer is the most frequent cause of death among women between the ages of 45 and 65 and is second among men of the same age. Cancer ranks third as a cause of death, only heart disease and tuberculosis have higher death rates. Of 100 boys ten years old, the probability is that more than eight will eventually die of cancer. Of 100 girls ten years old more than eleven will eventually succumb to this disease.

The present accepted therapeutic methods for the treatment of cancer are surgery, radiation, diathermy and cautery. It is recognized that these methods, under the most skillful hands, obtain only about 30 per cent of cures of all cancer and in this is included the basal cell epithelioma which responds favorably to appropriate treatment in 95 per cent of cases.

A careful study of the cured cases reveals the fact that the majority of them were treated when the disease was localized. Thus our hope for improving our statistics lies in the fact that we must see the cases in the early stages of the disease, recognize them and institute prompt measures for their proper treatment. This may

be accomplished first by educating the laity to recognize precancerous signs or lesions and the necessity of immediately consulting their physician. Secondly, to impress upon the medical man his responsibility in this matter when consulted.

In this country we have the American Society for the Control of Cancer which is doing wonderful work in educating the people to realize the importance of consulting their physician upon the first appearance of any abnormal lesion. Thus the responsibility for the recognition and prompt treatment of early cancer is being placed more and more upon the medical man. It is concerning this phase of the cancer problem that I wish to discuss with you.

Naturally, the proper place to begin an educational campaign on a medical subject is the medical college. History bears this out. A marked advancement in the treatment of tuberculosis was not made until the medical student was thoroughly grounded in the early signs of this disease. "Inflammation of the bowels" almost disappeared from the medical map, when the student learned that there was such a disease as appendicitis and was taught its early signs and symptoms. Undoubtedly cancer will yield to a large extent, when the medical student is impressed with the importance of its early recognition and is taught its natural history, its early signs and the necessity of prompt action in the treatment of this disease.

### ETIOLOGY

An enormous amount of research work has been done during the past twenty-five years, in trying to solve the problem of the cause of cancer. Numerous organisms have been cultured from malignant neoplasms, some of which have been thought by their discoverers to be specific. However, none has received general confirmation and it is the consensus of

\* Read before the Medical Students of the University of Buffalo May 4, 1926.

opinion among the foremost research workers in cancer, that this disease is not of infectious origin

Cancer has been produced artificially in animals by several different methods, such as the painting and the injection of tar and other chemicals, the feeding of nematodes and eggs of cestodes and also the application of X-rays. All of these procedures depend upon the factor of chronic irritation. However, not all the animals treated develop malignant disease so there must be an element of a special tendency toward cancer in those that do. The most generally accepted theory of the origin of cancer today, is a two-factor one. (1) An extrinsic irritation, usually long continued and (2) a hereditary tendency. Much experimental evidence can be brought forward to substantiate this theory.

### NATURAL HISTORY

Cancer, at first, is always localized and is amenable to cure if properly treated while in this stage. It is rarely an acute disease and is nearly always preceded by some chronic lesion or embryonic benign tumor. I do not believe that cancer ever begins in a healthy spot.

An unfortunate fact is that in the early stages, cancer is not accompanied by pain. Often upon inquiring why patients have waited so long before consulting a physician, the answer is given that as there was no pain, they did not think it was serious.

The beginnings of cancer are scaly areas, sores, unhealed wounds on the skin or the mucous membranes, elevated warts or pigmented moles, nodules under the skin or in the breast, swelling or pain in the bones or joints. These are all external and are easily seen or felt. Detection is somewhat more difficult with internal cancer. However, there is nearly always a distinct message in the form of discomfort, sensation of heat or weight, indigestion, pain or abnormal discharge. This latter is, as a rule, blood tinged. These early signs will be emphasized in the discussion of cancer of the various organs.

### DISSEMINATION

Cancer is the result of an abnormal proliferation of cells in an area which is the site of chronic injury. Although in some cases, the cells remain localized and produce a bulky tumor mass, in the majority of cases and ultimately in all, the malignant cells grow into the clefts and spaces of the surrounding tissues and eventually penetrate the lymphatic vessels and are carried to the neighboring lymph nodes where they proliferate and thus set up secondary deposits known as metastases.

It is due to this characteristic of the disease that we have the high mortality from cancer for wherever malignant cells have penetrated

and lodged, we have a potential cancer and this is frequently beyond the reach of the surgeon's knife or the safe penetration of the radiation wave. Thus again are we reminded of the necessity of an immediate attack upon all precancerous lesions and the site of early malignant disease.

It is a well recognized fact that today the majority of cases of cancer reach the surgeon in an advanced stage of the disease. It is usually the patient's fault, but there is evidence to show that the medical practitioner is not entirely blameless. We have had cases of rectal cancer come to the clinic who have never had a rectal examination by their doctor. In fact, some have been treated for hemorrhoids and pruritis ani, by salves, prescribed by the physician upon the patient's diagnosis. It is not rare to have a breast cancer patient tell us that her doctor had not considered the lump in her breast serious, especially if it had not shown evidence of recent growth. Many similar incidences might be cited.

It would probably be of most value if we consider the common places where malignant disease occurs and discuss the important facts in connection with each.

The word "cancer" should include all types of malignant neoplasms but this term has been restricted, by many, to malignant tumors composed of epithelial cells. Perhaps some other term could be substituted to include all "Malignant Disease" has been suggested, but this term would include Hodgkin's Disease, the leukemias and some others which are not accepted by all as neoplasms. Malignant neoplasms are generally divided into two groups viz, sarcoma and carcinoma.

The sarcomata comprise about 10 per cent of all malignant tumors. They are mesoblastic in character, occur more commonly in the young and usually metastasize by way of the blood stream. Therefore, the metastases are commonly found in the lungs.

The carcinomata comprise about 90 per cent of malignant tumors, originate in epithelial structures, usually begin to appear after 20 years of age and reach their maximum between 45 and 65. They commonly metastasize by way of the lymphatic vessels and thus the regional lymph nodes are the usual site of metastatic deposits. Although the word "carcinoma" is commonly applied to all malignant epithelial tumors, many restrict this term to those originating from glandular epithelium and use the word "Epithelioma" for malignant neoplasms originating in protective epithelium.

It would be impossible in the time allotted to this lecture, to consider all the organs which may become the site of cancer. A brief review of only the more important ones will be attempted.

### STOMACH

Cancer of the stomach is the most frequent cause of death from malignant disease. It occurs nearly equally in both sexes. The average reports of cures is about 5 per cent. Carcinoma of the stomach is one of our most difficult problems, for nearly half of the cases are well advanced before they have symptoms which urge them to seek medical advice. The other half have symptoms of indigestion which are so common among civilized people that often little attention is paid to them. Nearly all the cases that remain well after operation are either of the type that remains localized for long periods or are early ones that are discovered at operations for gastric ulcer. Patients past 30 who complain of chronic indigestion should have a thorough examination consisting of radio-grams, gastric analysis and the examination of the stools for occult blood.

### UTERUS

Cancer of the uterus causes nearly 13,000 deaths in the United States each year. When we consider that 35 per cent of this type of malignant disease is cured, one cannot help but be impressed with its frequency. 90 per cent of uterine cancer has its site in the cervix and it is the type that affects younger women. As cervical cancer occurs almost exclusively in married women, it is reasonable to presume that injury to the cervix is intimately associated with its development.

As we are prone to look upon cancer as a disease of middle life, I wish to warn you, that here is a type that may occur very early, that is in the twenties. We had two patients in our hospital at the same time, both under 21, who were suffering from well advanced uterine cancer.

If uterine injuries play a role in the causation of cervical cancer, it is clearly our duty to be on the lookout for such lesions and to insist upon their immediate repair.

In view of the frequency of cervical cancer, I believe that the medical practitioner should make it a rule to examine carefully, at least once a year, the cervix of all the married women among his clientele. Any changes observed in the menstrual periods, especially a blood-tinged discharge between them, demands a thorough examination, as this is one of the early signs of beginning cancer of the cervix.

### BREAST

Theoretically we should have no deaths from cancer of the breast for the disease is early discernible and is susceptible to complete removal. However, only about 25 per cent of the persons afflicted with breast cancer survive the five year period.

The histories of the cured cases, show, in the majority of them, that the disease had remained localized. Thus death usually occurs from metastases. How are we to reduce the mortality from breast cancer? First we must educate the woman to consult her physician the moment she observes any abnormal condition in her breast. Secondly, the consulted physician should recognize his responsibility in the matter. Any single lump in the breast of a woman past 25 demands the immediate attention of a competent surgeon. Another point which I wish to stress is that the patient should be warned not to handle the tumor nor let anyone else do so, for we have experimental evidence to show that metastases can be made to occur prematurely by massage of a malignant tumor. Thus the physician himself should realize and thus make his examination as brief and gentle as is possible.

Cancer of the breast rarely occurs before the age of 25. It is as frequent in single women as in married ones, although in the former it occurs at a more advanced age. It is intimately associated with chronic mastitis and some recent experiments seem to show that stagnant milk plays an important role in the origin of this disease. In connection with this, it might be well to call your attention to the fact that cancer of the breast is second in frequency among English and American women, and it is next to last among Japanese women. It seems to me that this should be an argument to persuade women to suckle their young. In any event, it should be an indication to empty the breasts of those women who will not or cannot nurse their offspring.

### INTESTINES

The great majority of intestinal cancer occurs in the colon and rectum, the small intestine being singularly free from this disease. In the colon the most common sites are at the flexures which correspond to areas of mechanical injury. Of these the caecum and the sigmoid flexures are the most important. About one half of intestinal cancer is found in the rectum. Chronic constipation and blood in the stools are two common symptoms of intestinal cancer. On account of the medical man's keenness for the region around the appendix, caecal cancer is often discovered fairly early but as much cannot be said for rectal and sigmoid cancer. There seems to be a natural aversion for the practicing physician to make a thorough rectal examination. This is regrettable, for cancer of the lower bowel often remains localized for long periods and if recognized, is amenable to surgical treatment. Let me, therefore, urge you to realize the importance of not only making a digital but also a proctoscopic examination of all your pa-

tients in the cancer age, who complain of rectal disturbances

### MOUTH

Under this heading we will consider the lip, the tongue and the lining of the mouth. Cancer in these locations occurs largely in men, especially those who use tobacco to excess. However, cancer of the mouth does occur in women and also in men who do not use tobacco. But a significant fact in this connection is that in certain parts of India where both sexes have the habit of chewing the betel nut, cancer of the mouth is as frequent among the women as it is among the men. As a matter of fact, mouth cancer is the most common manifestation of this disease in India.

Cancer of the lip occurs most frequently upon the lower one and if the man is a pipe or cigar smoker, its site corresponds to the area where the pipe is held. A pimple or slight sore which does not heal is usually the first sign. Often the malignant lesion is preceded by a white patch called leucoplacia. Leucoplacia is followed by cancer in about 25 per cent of the cases. It is nearly always due to smoking and the complete abstinence from tobacco will cause this lesion to disappear. Lip cancer is a preventable disease for it is nearly always accompanied by a sufficient warning.

Cancer of the tongue is a very fatal disease because the mucous membrane from which it springs lies directly upon the muscle, and therefore, has no submucosa. Thus the malignant cells gain early entrance into the lymphatic channels.

Cancer of the tongue is also associated with excessive smoking and leucoplacia is frequently found upon this organ.

However, ragged teeth and a dirty mouth are probably more important. I have never seen a case of cancer within the mouth, where the teeth were in good condition. Our experience shows that over half of our mouth cases give a positive Wassermann reaction. A chronic ulcer on the edge of the tongue is always a precancerous lesion.

What has been said for the tongue, also applies largely to the lining of the mouth.

### SKIN

Skin cancer probably never begins in a healthy spot. It is usually preceded by a diseased area, as an unhealed ulcer, a pigmented mole, an ulcerated wart, a burn, lump or nodule. These conditions often persist for long periods before they undergo malignant change. It is, therefore, our responsibility and our duty to per-

sue patients with such lesions to have them attended to at once.

Cancer occurs in the skin in two forms, viz., (1) the basal cell epithelioma, and (2) the pearl cell epithelioma. The basal cell type is comparatively benign, rarely metastasizes and can be cured in 95 per cent of cases. It is nearly always confined to the face. It has its origin in the glands of the skin. The pearl cell type, on the other hand, is more malignant, metastasizes freely and is the type that originate at the edges of chronic ulcers, old burns, etc.

A type of cancer that occurs on the skin and takes its origin from pigmented moles, is the malignant melanoma. This is a very malignant type of tumor for it metastasizes early and very extensively. Elevated pigmented moles, especially those subject to irritation, should be removed.

### BONE

I include here sarcoma of bone for our results in this type of malignant disease have been discouraging. The malignant cells get into the blood stream very early and are carried to the lungs. Amputation is, therefore, without avail after metastasis has occurred.

Our hope in bone sarcoma is the early recognition of the disease. The warnings are local pain, swelling or impaired function. An immediate X-ray picture is imperative. As a matter of fact, I believe that there should always be an X-ray picture taken after any bruise or injury to a bone or joint.

### CONCLUSION

As medical students you are now preparing yourselves for your life work. After you get into practice you will often wish that you had paid a little more attention to this or to that subject while in college and will regret that you did not make the most of opportunities offered you. In your hospital experience you will have many opportunities to observe and study cancer cases, but not many early ones, nor many precancerous lesions. Take time to learn all you can about the natural history of cancer, the lesions that are liable to become cancerous, and the early signs and manifestations of this disease. It will also become your duty to aid in the educational propaganda, especially among your own patients, warning them of the danger of delay and pointing out the probability of a cure if this disease is treated in the early stages. Upon you will rest part of the responsibility for the prevention and reduction of the mortality from this modern scourge.

## CAESAREAN SECTION BY A NEW METHOD\*

By GEORGE L BRODHEAD, M D, EDWIN G LANGROCK, M D, and  
CHARLES S B CASSASA, M D, NEW YORK, N Y

THE purpose of this paper is to present for your careful consideration a new method of performing Caesarean section. This new procedure is not an improvement on the classical Caesarean section, but an operation to be done on those patients in whom a classical section would be fraught with the greatest dangers, namely those in which (1) The patient has been in labor a long time, (2) The membranes have been ruptured for many hours, (3) Numerous vaginal examinations have been made, (4) Attempts at delivery per vaginam have been made, (5) There is a suspicion of uterine infection, (6) There is intercurrent infectious disease. In this class of cases, the operation we are about to describe will give the best result for the mother.

The mortality of classical Caesarean section is far from negligible as evidenced by Reynold's<sup>1</sup> statistics in which he found it to be "12% when done before labor, 38% when done early in labor, and 12% when done late in labor." Routh<sup>2</sup> gives a mortality of "29% when the classical operation was performed before rupture of the membranes, 108% after their rupture and 343% following repeated examinations or previous attempts at delivery." Williams<sup>3</sup> states that "no matter how good the operator or how perfect his technic, it would appear that the mortality even in apparently uninfected women, will depend in great part upon the period of labor at which the operation is undertaken." According to Newell<sup>4</sup>, patients who have been repeatedly examined during labor, even under strict asepsis, in whom the membranes have been ruptured for a considerable period, in whom attempts have been made to induce labor by means of a bag or bougie, or in whom serious attempts at pelvic delivery have been made by operative means, are poor risks for the classical Caesarean section. This class of patients we shall call the potentially or presumably infected class.

If a classical Caesarean section is done on a patient in this presumably infected class, her death is usually due to peritonitis. Loss of life from hemorrhage or causes other than peritonitis is not considered in this paper, for these maternal deaths the new operation we shall describe, does not prevent. Peritonitis following Classical Caesarean section is usually caused in two ways: first by contamination of the peritoneal cavity with the infected uterine contents, amniotic fluid, blood, fetus, placenta, etc., at the time of operation, the so-called initial spill, and second, leakage of infected lochia from an infected uterus, through the uterine suture line. That the abdominal cavity may be infected by the initial spill is self-

evident. If a quantity of germ-laden amniotic fluid or blood from the interior of the uterus comes in contact with the peritoneum, as it does no matter how carefully the peritoneal cavity has been protected with abdominal pads, this entrance of infected material cannot be considered innocuous.

Newell<sup>5</sup> states that "in patients who have been repeatedly examined during labor, it is almost certain that infective organisms have been introduced into the uterine cavity, and contamination of the peritoneum or infection of the uterine wound is probable." Newell<sup>6</sup> further states that "it is a well recognized fact that premature rupture of the membranes predisposes markedly to infection of the amniotic cavity." Slemons<sup>7</sup> has shown that infective organisms not infrequently invade the placenta and are even transmitted to the fetus. It is evident therefore that a patient is exposed to great danger of peritoneal infection when under such circumstances she is subjected to a classical abdominal delivery, for it is very difficult to avoid infection of the peritoneum when the uterus is opened.

Polak<sup>8</sup> fears this initial spill, for he wrote in describing the Hirst operation that "the general peritoneal cavity in this operation is not contaminated by any leakage of liquor amni." Polak also states that "women who are long in labor with ruptured membranes have numberless bacteria in their uteri, many of which are pathogenic, the classical celiohysterotomy exposes the peritoneum to infection from this source."

That the peritoneal cavity may be infected by leakage through the uterine suture line by infected lochia is also self-evident, for, a uterine wound bathed in infected lochia with perhaps some of the stitches disintegrated and here and there a portion of the uterine wound wide open, must necessarily be the causative factor of a general spreading peritonitis.

An operation therefore in order to insure the patient against peritonitis from these two causes must first, absolutely prevent the initial spill from entering the peritoneal cavity, and must, second, so place the sutured wound in the uterus that any leakage of infected lochia through it, will not enter the peritoneal cavity. In the operation, the technic of which will now be described, both of these objects, have been accomplished.

Some years ago, Hirst<sup>9</sup> modified the operation devised by Veit<sup>10</sup> and was successful in excluding both the initial spill and the subsequent leakage from the peritoneal cavity. Hirst incises the visceral peritoneum on the anterior surface of the uterus in the mid-line, detaches it from the uterus in the lower uterine segment, opens the uterovesical space and with retractors crowds the blad-

\* Read at the Annual Meeting of the Medical Society of the State of New York, at New York March 30, 1926

der downward and forward. This detached incised uterine peritoneum he unites with the parietal peritoneum, thus leaving the denuded anterior uterine wall exposed through which he can empty the uterus and yet prevent any of the uterine contents from entering the abdominal cavity. In repairing the wound, he sews the united visceral and parietal peritonea over the sutured myometrium thus preventing any leakage from the uterine wound into the peritoneal cavity.

This modification by Hirst of the Veit operation made it possible to deliver potentially infected patients by the abdominal route without danger of peritonitis. The operation, however, was not universally adopted, and we believe that we have so altered and improved the method of Hirst and Veit, that we have made it possible to do the operation so quickly and easily that it should be the method of choice in performing a section on a presumably infected patient.

Dr Charles S B Cassasa, Associate Attending Surgeon at the Harlem Hospital, devised in 1916 the method which we are about to describe. He reasoned that the procedure was a safe one from the surgical standpoint and his enthusiasm and cooperation prompted us to try it, with the result that in thirty cases, all manifestly unfit for the classical Caesarean section, we had no death from peritonitis.

The purpose of the operation is to secure a quadrilateral area on the anterior surface of the uterus, through which the baby may be extracted and at the same time, have this area excluded from the general peritoneal cavity. This quadrilateral area, six inches long and three-quarters of an inch wide, is obtained by suturing the peritoneum of the anterior abdominal wall to the peritoneum on the anterior surface of the uterus. The procedure is as follows:

A para-median incision is made about seven inches in length beginning at a point one inch above the navel and extending downward toward the symphysis, the peritoneal cavity is opened in the usual manner. A stitch of plain catgut is placed horizontally at the upper angle of the wound, uniting the peritoneum of the anterior abdominal wall to the anterior surface of the uterus. This stitch is tied and a clamp placed on the shorter end, this clamp to be used later as a tractor. With a second needle and suture a stitch of plain catgut is then similarly placed at the lower angle of the wound, horizontally, uniting the peritoneum of the anterior abdominal wall to the anterior surface of the uterus. This stitch is also tied and a clamp placed on the shorter end, this clamp also to be used later as a tractor. These two stitches form the upper and lower limits respectively of the quadrilateral space. The vertical limb of the quadrilateral on the right side is made by utilizing the long end of the first suture which was placed at the upper angle of the wound and sewing downward to the lower angle of the

wound. This is a continuous overlapping suture and is placed three-eighths of an inch from the cut edge of the peritoneum of the abdominal wall, and unites the parietal peritoneum to the anterior surface of the uterus. The vertical limb of the quadrilateral on the left side is similarly made by utilizing the long end of the second suture which had been placed at the lower angle of the

Figure 1 Showing incised parietal peritoneum. Visceral peritoneum on anterior surface of the uterus showing through. Parietal and visceral peritonea united by anchor suture at upper and lower angles of the wound.

wound and sewing upward to the upper angle of the wound, three-eighths of an inch from the cut edge of parietal peritoneum, thus completing a quadrilateral area six inches long by three-quarters of an inch wide, which area is now excluded from the general peritoneal cavity. This excluded area is covered by two flaps of parietal peritoneum, each three-eighths of an inch in width, separated in the mid-line by the original peritoneal incision which was made in opening the peritoneal cavity.

The uterus is opened, the child extracted by the breech, one c.c. of pituitrin is given, and the placenta is removed in the usual manner. The uterine cavity is then packed with iodoform gauze. The uterine musculature is closed with a continuous or interrupted No. 2 chromic gut stitch. A continuous suture of plain catgut is then used to close the peritoneal incision in the uterus. The two flaps of parietal peritoneum

Figure 2 Showing the parietal peritoneum being sutured to the visceral peritoneum on the anterior surface of the uterus by a continuous, overlapping stitch placed 3-8 of an inch from the cut edge of parietal peritoneum.

which have been described covering the excluded area of the uterine wall are then sutured in the usual manner. The remainder of the abdominal wound is then closed.

Before adopting this technic we operated upon one patient in the following manner. The parietal peritoneum was sewed to the anterior surface of the uterus without opening the peritoneal cavity, but, though the woman made an uneventful recovery, there is a possibility of injuring a loop of intestine which might be present in front of the uterus, and the method was abandoned.

The advantages of this method are many. It is very simple, and requires neither unusual skill nor practice. There is no dissection of the visceral peritoneum from the anterior surface of the uterus, which takes time and gives a raw surface, which often bleeds profusely. The bladder region is not entered, so that there is no danger of injuring it or of having post-operative vesical complications. There is absolutely no initial spill into the peritoneal cavity of uterine contents, nor is there subsequent leakage from the uterus into the peritoneal cavity. Patients may be given a longer test of labor and still be delivered by this method when classical section would be contraindicated. As a result of the longer test of labor, fewer Caesarean sections will be necessary. In spite of the fact that the membranes have been

ruptured many hours, and that numerous vaginal examinations and attempts at delivery from below have been made, these patients may still be delivered safely by Caesarean section performed by this method. Craniotomy on the living child need never be done with this operation as its alternative. The post-operative convalescence is remarkably free from shock and abdominal distress, especially tympanites. This is due to the fact that the intestines are not traumatized by handling or the use of abdominal pads, in fact, the intestines are rarely, if ever, seen. At no time during the operation do the hands of the operator, or his assistant, or anything except the threaded needle, enter the peritoneal cavity. The ease and speed with which the uterine and abdominal wounds are closed adds materially to the safety of the patient.

There are no disadvantages of this method. The one objection which may be raised is that we leave the patient with a high fixation of the uterus. In this series, we did not have a patient that was in any way inconvenienced by this fixation. The patients were seen from one to seven years after the operation and there were no com-

Figure 3 Suture of the parietal peritoneum to the visceral peritoneum on the anterior surface of the uterus completed.

Small diagram Shows overlapping stitch making suture line water-tight.

plaints. The menstrual function was unaltered and many of the patients became pregnant and carried their babies to term normally. If this fixation leaves the patient symptom free with unimpaired function of the organs involved, one is justified in making in her an anatomical change which makes it possible to do a life saving operation. If subsequently, an elective Caesarean section is done (as will usually be necessary because the most common indication for the operation was contracted pelvis), the fixation may be released with the greatest ease in a very few moments, by cutting through the fixation band. The uterus drops into the abdominal cavity, and the

Figure 4 Showing the uterine wound closed and the parietal peritoneal flaps being sutured.

classical operation is then proceeded with. We have recently performed elective Caesarean sections on two patients, previously operated upon by this method, and succeeded easily in removing the fixation band.

We operated upon thirty patients by this method. In each case a classical Caesarean section was manifestly contra-indicated. To cite a few examples: Patient No 1 in the series, had a contracted pelvis, 48 hours of labor, attempts at bagging and delivery prior to admission. Patient No 2 had a contracted pelvis, 30 hours of labor, 3 doses of pituitrin and 3 attempts at forceps delivery, prior to admission. Patient No 15 had a contracted pelvis, about 28 hours of labor, was in the care of a midwife, and a forceps delivery had been attempted prior to admission. Patient No 20 had been in labor 3 days, with uterine inertia, numerous vaginal examinations had been made, and the membranes ruptured  $2\frac{1}{2}$  days before admission. Patient No 21 was a Primipara in poor condition with concealed accidental hemorrhage, the cervix admitting one finger, and a Bag had been introduced before admission to the Hospital.

A number of the patients came into the hospital with elevated temperature and pulse rate. During the puerperium many of these patients had a temperature of from 101 to 103 degrees for a variable number of days, due to post partum infection. We believe that classic Caesarean section in this series would have given a high maternal mortality. In these thirty cases we did not have a single death from peritonitis. The one death in our series was due to post-partum hemorrhage and occurred in a patient who was in very poor condition at the time of operating. In conclusion, we believe that this operation has been so successful that it should be the operation of choice in potentially infected cases.

## THE DIAGNOSIS AND TREATMENT OF BRAIN TUMORS\*

By WALTER E DANDY, M D, BALTIMORE, MD

ALL lesions become more frequent as our acquaintance with them grows. If we hark back but a very few years, appendicitis was unknown, then very rare, and finally a very common ailment. The same story is true of any number of lesions. The great educator of true perspective is necropsy and operation. Brain tumors are passing through the rare stage because neither necropsy material nor operative inspections have checked mistaken diagnoses. But in a few clinics intensive studies have shown not only that brain tumors are among the most frequent tumors of the body, but during the first six decades, particularly from the second to the fifth decades, tumors are among the most common afflictions of the central nervous system.

The results of the long struggle in the solution of appendicitis should teach us much about the fundamental treatment of brain tumors, and prevent many of the sad chapters in its story when told in later years. Two accomplishments have transformed a prohibitive mortality in the treatment of appendicitis into one which should be practically nil: first and foremost, an early and accurate diagnosis, and second, an early and efficient operative procedure which eradicates the cause.

In the treatment of brain tumors, the same two factors are all-important, and in addition there is the third great factor—localization of the tumor. Although the diagnosis and localization of appendicitis are nearly synonymous, the same is far from true in brain tumors. In fact, the localization of brain tumors has been the most difficult phase of this complex neurological problem.

It is doubtless known to you all that tumors as large as one's fist are still compatible with life and without giving the slightest evidence of their situation. For many years it has been possible to know that a patient was afflicted with a tumor, but we have not been able to tell where it was located. With such inadequate information, it is clear that operative results must be very poor. Without accurate information, I should venture the assertion that in the hands of the very best operators, less than one-third of all explorations for brain tumors would actually disclose the tumor at first operation. In fact, so discouraging have been explorations for tumors of the brain, that, except when the location of the tumor seems clear, the palliative decompressive operation has become more or less routine. Obviously, such treatment is most

unsatisfactory. There is only one way to cure a patient with a brain tumor, and that is by a complete extirpation of the growth by operation. Decompressions have been justifiable only because the location of the tumor has been unknown. If the location of the tumor is known, any treatment which delays or is palliative is no more justifiable than delay or palliation in appendicitis.

Although the rate of growth of brain tumors is variable, a fatal outcome is almost inevitable. But we have many warnings of this impending calamity. Tumors cause headache, destroy vision, produce paralyses, convulsions, speech and mental and other disturbances, and most of these changes are progressive. The great hope for patients afflicted with brain tumors lies in the earliest possible diagnosis. To do this, it is incumbent upon us to suspect a tumor when any symptom or sign referable to the central nervous system makes its appearance. Fortunately, it is now possible by the use of cerebral pneumography—i.e., roentgenography of the brain after the injection of air into its ventricles or subarachnoid spaces—to diagnose and also to localize practically all brain tumors which cause pressure, and in the early stage of the tumor's growth. This being possible, the problem of handling brain tumors is greatly simplified.

The treatment of tumors is now reduced to a single simple formula. Complete extirpation when the nature and location of the growth make this possible, and when impossible of removal, then and only then to produce the maximum decompression for palliation. Unfortunately, some brain tumors, by virtue of their infiltrating character, do not permit extirpation. In other instances, removal is precluded because of the invasion of the brain-stem, speech centers, or other vital parts of the brain. There are, however, many nonencapsulated growths in silent areas of the brain which, if detected early, can be completely removed. The so-called silent areas of the brain were formerly the greatest handicaps to cerebral surgery because they prevented diagnosis or localization of the growths owing to the absence of signs or symptoms. Formerly, it was necessary to perform palliative operations until the tumor grew beyond the confines of the silent brain and produced paralyses or other focal destructions of the contiguous brain with recognizable functions. Now these silent areas are the greatest assets for the success of brain surgery, for, the localization now being possible in another way, extirpation of the growth can be done with contiguous silent areas of the brain,

\* Read at the Annual Meeting of the Medical Society of the State of New York at New York March 30 1926

when necessary, and still leave the patient without noticeable defects

I have said that practically all brain tumors should now be localized and at once. Brain tumors give rise to two types of signs and symptoms: (1) localizing symptoms and (2) general pressure symptoms. If the former are present, the localization is automatically made. Their consideration need not detain us. But the overwhelming proportion of brain tumors give rise to so-called pressure symptoms, and it is to the consideration of this difficult problem of localization that I wish particularly to call your attention. As you know, the craniovertebral chamber is a closed and fixed space and its contents—blood, cerebrospinal fluid, and brain tissue—are almost totally incompressible. For this reason, a new growth is tolerated only by a compromise with these intracranial contents, and this compromise gives the warning signs, headache, nausea and vomiting, choked disc, etc.

Probably all brain tumors which produce intracranial pressure, produce (as an expression of this compromise) changes in the size, shape or position of the ventricles and subarachnoid spaces of the brain. If the fluid from these spaces is removed and air is substituted in its place, these changes in size, shape and position will be accurately registered in roentgenograms of the head. It is, therefore, clear that if these alterations are known, the location of the cause which produces them (the tumor) can be deduced. I will now show you a series of lantern slides which will explain the localization of brain tumors from every part of the brain. In many instances the localizations have been so precise as to permit transcortical incisions of great depth to find the tumor at operation, and often successfully to remove tumors which otherwise could never be found except at necropsy.

I should not wish to leave you with the impression that it is a simple and harmless procedure. Unfortunately, it is the reverse. It is both complicated and dangerous. The interpretation of the air shadows is difficult and is all dependent on the intimate knowledge of intracranial anatomy and physiology. Its danger is shown by the fact that I have had three deaths in my first 100 injections. However, in over 400 since then, there has been none. This is owing to the fact that I have learned how to eliminate danger. Air is an irritant. When the ventricular channels are blocked, its absorption is prevented; a serosanguinous exudate results from its irritation, and this produces a marked accentuation of pressure symptoms. Many patients are so ill that this additional pressure could not be tolerated. To prevent this complica-

tion, the air should be removed as soon as possible after the skiagrams are completed. If the quantity of air injected is large (30 c.c. or more) either the original ventricular fluid or saline solution may be replaced. In safe hands, the procedure is now without great danger. It seems inadvisable, at least at the present time, that a risk so great as the use of air requires, should be assumed except by a competent neurological surgeon.

Lantern slides were then shown as follows:

(1) *Tumors of the frontal lobe*—The localizations were made by dislocation of both lateral ventricles and the third ventricle away from the tumor (anteroposterior view). Often the homolateral ventricle, and at times also the third ventricle, were obliterated. The third ventricle, when present, takes an oblique instead of a normally upright position (anteroposterior view), ventricular filling defects on the side of the tumor (lateral views).

(2) *Tumors of the temporal and parietal lobes*—Practically the same pictures as frontal lobe tumors, though with more pronounced filling defects. There may be elevation of the descending horn of the ventricle in temporal lobe tumors. Parietal tumors may disclose the body of the ventricle downward, broaden its diameter and shorten its height, or narrow its diameter and increase its height, depending on the exact position of the tumor.

(3) *Tumors of the occipital lobe*—The lateral dislocation of the anterior horns of the ventricle (anteroposterior view, occiput down), is less than in frontal, temporal and parietal tumors, and may even be absent. Filling defects of ventricles and alterations in size, position and shape of the ventricles.

(4) *Ventricular tumors*—Filling defects in ventricles and evidences of hydrocephalus from closure of the ventricles. A small tumor in the body of the lateral ventricle showed a normal ventricle anterior to the tumor and hydrocephalus of the ventricle posterior to it. The sharp anterior and posterior margins of the tumor were shown by the abrupt lines of termination of the air shadow. A tumor of the third ventricle showed a bilaterally symmetrical hydrocephalus, but with no communication between the two lateral ventricles and with absence of the third ventricle.

(5) *Tumors producing symmetrical dilatation of the lateral ventricles with intercommunication*—This line of tumors included (1) supratentorial tumors growing upward and occluding the aqueduct of Sylvius, (2) pineal tumors, (3) tumors contiguous to the pineal and the third ventricle, (4) tumors in various parts of the posterior cranial fossa (cerebellum, cerebellopontine angle, brain-stem and fourth ventricle). All of these tumors block the inter-

or fourth ventricle. In one instance a shadow of a suprapituitary tumor was seen in the air background of the dilated ventricles, its presence could not be detected except in the presence of air. This has been an important finding in many other tumors situated elsewhere. In another case of suprapituitary tumor, the tumor had grown lateralwards and blocked one lateral ventricle and partially obliterated the third ventricle.

A pineal tumor was shown causing dilatation of the ventricles with partial obliteration of the third ventricle, and a large shadow of calcification in the air background.

An endothelioma arising from the leptomeninges near the pineal produced a great hydrocephalus of both lateral ventricles, partial obliteration of the third ventricle, and a

great filling defect of the left lateral ventricle.

Various tumors of the posterior cranial fossa produce dilatation of the third and both lateral ventricles. A case of cicatricial closure of the foramen of Magendie was shown (with dilated lateral and third and fourth ventricles). After a new foramen of Magendie had been constructed, the air could be seen in the cisterna magna and the cerebral sulci (indicating that the new foramen was patent several weeks after the operation). The patient has since remained well (now four years). Another case was shown in which a tremendously dilated cisterna interpeduncularis extended upward and produced a great filling defect in the left lateral ventricle. Both lateral ventricles were of enormous size owing to the obstruction in the cisterna.

## DISSOCIATIONS—THEIR ROLE IN AMNESIA, MULTIPLE PERSONALITY, OBSESSIONS AND SOMNAMBULISM

By ROBERT KINGMAN, A M, M D, F.A.C.P, BROOKLYN, N Y

MODERN psychology uses the term dissociation to indicate states of mind common to all of us to some extent and in certain individuals existing to a degree that is accountable for the presence of such interesting and related phenomena as somnambulism, double personality, amnesia and automatic writing. In turning an introspective eye on one's own field of consciousness it appears like a stream of thought progressing upon a uniform plane toward some definite end, very much as the story of a moving picture film unrolls itself reel by reel before our outward vision. The ideas and sensations and feelings that preoccupy us at any given moment do not appear like separate entities moving independently of each other at different rates of speed toward various objectives, but all seem blended together for some common purpose and to be moving along at about the same velocity like objects floating downstream with the current.

The mind, to be sure, may be found occupied with the varied details of a business problem and then a few minutes later with plans for a coming vacation. But the two ideas do not occupy the field of consciousness at the same time and there was some hidden link that led from one to the other and bridged the gap between the two subjects. As thought flowed along one idea gave place to the other, and because of the hidden thread common to both, no actual break in continuity actually took place. Accepting this appearance for the reality, the older psychology was far from conceiving that the mind could split up into chunks of various sizes, each one independently busied with its own particular interest and entirely oblivious to the activities of its neighbors.

Nevertheless this is just the way in which the

mind frequently does act. A piano player, for instance, may occupy himself with a piece of music that he has never seen before, playing with appropriate and varying expression, and be busily engaged in his mind at the same time with the problem as to whether or not he should vote for the referendum on prohibition. The two lines of thought involved, one a political issue and the other a musical interpretation, are almost entirely independent of each other, but going on at the same moment. And just as with the cobbler who plies his trade while thinking of his sick wife, the field of consciousness is more or less divided into two parts and some degree of dissociation of consciousness must exist. The dissociation is partial and temporary, and as either or both activities may be abandoned at will, they are under the control of the subject. It is where this control no longer remains that the marked degrees of dissociation are found.

Psychology uses the term suggestibility to indicate a condition of the brain in which the individual adopts whatever occurs to his mind without exercising a normal amount of judgment and before investigation of the facts. Suggestible persons are the victims of every whim and fancy that may cross their minds, and they take up every fad and every idea that comes to their notice through the press or the conversation of their friends. Their instability and pressure for immediate action leaves no time for reflection as to whether the advice may be good or the end desirable. No sooner heard than done is their motto.

There are two conditions in which suggestibility exists to a marked degree—one is hysteria and the other is hypnosis. A subject in the hypnotic state will make love to a chair if told that it is a girl,

will collect mosquitoes if told that they are butterflies, or jump out the window if told that the room is on fire. There is no interval between hearing the suggestion and putting into operation the action that would be appropriate if it were true. Hysterical people are similarly prone to act upon suggestions coming from without, and are also particularly liable to be the subjects of auto-suggestion, that is, the wildest and most illogical ideas that may pass through their minds are accepted as true without question or reflection and acted upon in the same manner as suggestions coming from another person.

Automatic writing, while occasionally found in normal people, occurs in its most perfectly developed form among hysterics. It is not in the least necessary to invoke the aid of spirits to produce a specimen. If the attention of an hysterical patient be diverted by conversation, and a pencil placed between the fingers of his right hand, a third person, by whispering questions in his ear may receive written answers to these whispered questions, while the patient is continuing his conversation on an entirely different subject. Not only will the patient be altogether unconscious of what his hand is doing, but he is often entirely ignorant of the events described in writing. This experiment is used to resuscitate buried memories, for the explanation of his lack of knowledge when questioned on matters that he automatically answers in writing is to be found in the fact that such matters have to do with episodes in his past life which have been completely suppressed and forgotten. In fact this loss of memory for a definite section of the past, often of long duration and for events of the utmost importance, is a characteristic symptom of hysteria.

The explanation is simple, for the apparently extraordinary manifestation of automatic writing is merely an exaggerated form of the dissociation present in the piano player's mind when he thinks of two things at once. A more complete dissociation has taken place in which one activity of the mind remains under control of the subject, while the other does not. The field of consciousness has been divided into two distinct parts, one engaged in conversation and the other with the matters about which the patient is writing. Each portion carries on complicated mental processes, not only independently of each other but unaware of each other's existence. Here are two sets of memories with no connecting link, and two smaller minds instead of one large one, engaged in two different occupations.

We generally associate somnambulism with the sleep-walking of small boys who wander about the house or climb out of windows in a sort of trance after they have been put to bed at night. But grown-ups suffer from somnambulisms and in the daytime, for the condition includes those spells in which a person suddenly drops his ordi-

nary train of life and commences to re-enact or continue some previous experience. One of the best known somnambulisms is that recorded by Dr. Janet under the case designation of "Irene." This girl had nursed her mother through a long illness ending in death under circumstances that were extremely painful. The shock to her mind was profound. She soon, however, ceased to show any emotion when her mother was mentioned and was even reproached by her relatives for her unfeeling attitude. At about the time that she appeared to show no further regret for her mother she became subject to seizures which came on suddenly in the midst of talking or working. She would drop whatever she was doing and re-enact every detail of the death scene with the fidelity of an accomplished actress. During this drama she was entirely unconscious of every thing going on about her, heard nothing that was said to her and saw nothing else but the imaginary scene in which she was taking part. The somnambulism would then end as suddenly as it had begun, and she would return to her former occupation at the point or the word where it had been interrupted, unaware of any interval. In the intervening normal state she not only knew nothing of her somnambulist performance, but had also forgotten everything connected with her mother's illness and tragic end. Her conscious memory showed a gap from the exact moment when the somnambulism began to the exact moment when it ceased. A lapse of this sort is known as amnesia.

The dissociation of consciousness in the case of Irene was not into two separate simultaneously present portions as occurs in automatic writing, but into two portions which succeeded and alternated with each other. The difference may be visualized by saying that in automatic writing the split is longitudinal, which allows two parallel activities to be carried on separately at the same time, like two streams flowing side by side, each impervious to the other. In somnambulism, the splitting is horizontal, one phase of consciousness is cut clear across in its full width. An alternate phase thereupon supervenes and takes full charge until the first phase is as suddenly resumed where it was dropped, and with no recollection of there having been an interlude. The longitudinal splitting is like two moving picture stories being thrown on a screen side by side and moving along together, while the horizontal split presents two pictures alternately, first a reel from one and then a reel from the other.

Perhaps the most interesting bit of knowledge that has been recently established in connection with these and other dissociations is that they are not haphazard occurrences, but a far-sighted and purposeful attempt on the part of nature to save the mental balance of the individual in whom they appear. The mind is built so that certain portions can be split off into thought-tight compartments

for the same reason that a ship is constructed on the water-tight compartment plan. If the ship is in danger from flooding, the doors of one or more compartments are closed either automatically or from the bridge and the water which would otherwise overwhelm and sink the boat is confined within certain limits. In exactly the same way, ideas to which are attached such painful feelings or such dangerous thoughts as might wreck the reason of the individual if allowed full and unrestrained freedom, are split off from the main body of the mind and enclosed in thought-tight compartments where they can do less harm than if left at large.

It was not because she was hard-hearted that Irene ceased to remember her mother, but because her grief was so painful that it would have wrecked her reason had nature not tied the whole subject up in a dissociated portion of her mind away from her conscious reach. And even then, so great was the struggle of this imprisoned portion to come again to the surface, that a compromise was found necessary and it was allowed to reappear from time to time in a sort of pantomime on the stipulation that no conscious memory should ever be aroused. Similarly, in cases of automatic writing, the matter thus elicited has had to do, at some time and in some way, with an unpleasant experience of some sort. The compromise entered into in these cases is not that the matter shall never be allowed to come into consciousness, but that it shall arrive there only by the secret route and in the covert manner of automatic writing, which will allow the individual the privilege of denying all previous knowledge of its existence.

Nature, ever on the alert against emotions and thoughts which would actually endanger the sanity of the individual, establishes a sort of censorship in regard to what shall and shall not be allowed to remain in consciousness. She has at her command a variety of protective devices, the choice of which in any particular case is determined by the seriousness of the situation. The phenomena of double personality and the persistent ideas known as obsessions are to be numbered among the safety-valves by way of which nature substitutes a lesser evil for a greater.

On January 17th, 1887, the Rev. Ansel Bourne, drew a sum of money from a bank in Providence and then entered a horse-car. He was not seen nor heard of again for two months. On the morning of March 14th, Mr. A. J. Brown awoke in a fright in his lodgings at Norristown, Pa., and called in the people of the house to tell him who he was. Brown had rented a small shop six weeks previously, stocked it with stationery, confectionery and small articles, and carried on his trade without seeming in any way unnatural or eccentric. But on the morning of the 14th he declared that his name was Ansel Bourne, that he knew nothing of shopkeeping, and that the last

thing he remembered was drawing money from a bank in Providence and entering a horse-car in that city. He believed that this had happened yesterday. This instance of double personality was originally described by Henry James and is a good example of a somnambulism in which the dissociated system is so extensive and the amnesia so complete that it is termed double personality. Even with the dissociated system in entire possession of the field of consciousness, the patient's behavior is normal and adapts itself thoroughly to his environment. But the condition actually differs from somnambulism only in the completeness and elaborateness of its development. The normal stream of consciousness has been suddenly broken across and replaced by a series of altogether different mental processes.

Unpleasant newspaper notoriety has been given to instances of persons who have alleged amnesia and double personality as an excuse for disappearing from home to escape some disagreeable or criminal situation of their own creation. Incidents of this sort have happened so opportunely as to cause the average man to doubt whether such a condition could arise without conscious feigning on the part of the fortunate victim. Nevertheless, authentic instances of double personality are not rare. It is to be noted that the Rev. Ansel Bourne had not committed any crime, nor was he in money difficulties. But he had been overworked and over worried. The crux of the matter usually lies just there. Nature helps those who cannot help themselves. She does not offer a ready means of escape to anyone who has robbed a bank or committed a murder. It is only when the mental and moral strain of some problem has long occupied the mind of an over-conscientious person and threatens to unbalance the reason that she steps in to solve the dilemma by offering temporary oblivion in the shape of one of her forms of dissociation. It is the victim of the round-peg-in-the-square-hole situation, the man who has long striven to measure up to the demands of a business or domestic drama for which he has neither the mental endowment nor the physical stamina, on whom she takes pity. Many a man could be a successful and contented shop-keeper like A. J. Brown, who would live a life of continual misery if called upon to take up the pastoral duties of Ansel Bourne. And many a man could live in peace and comfort with Mrs. Jones, who might be driven to distraction and amnesia by Mrs. Smith.

If the dissociation of double personality occasionally offers a refuge from overwhelming difficulties, that of obsessions often operates as a relief from small torments. An obsession is an idea which constantly recurs to the mind in spite of all efforts to banish it, or an impulse which causes one against their will to perform some irrelevant and inappropriate action. Touching every lamp post, or counting the steps, are common exam-

ples, and hours may be spent before the mirror struggling with the idea that the face is growing longer, or twenty physicians may be consulted because of an unfounded idea of tuberculosis. Minor varieties of obsessions are the melody that runs continually in one's head and the constant repetition of a name or a verse which refuses to leave us in peace. Such ideas and actions are indeed tormenting in themselves, but it is well to remember that they are not nearly as distressing as the ideas and actions for which they are acting as substitutes.

When obsessions are traced to their foundations, each one is found to be a symbolic or euphemistic method of avoiding an action or a thought with which our subconscious mind is busied, and which it is quite ashamed to allow to appear in consciousness. So that the touching of the lamp-post is a makeshift way of satisfying a longing to touch something that would be opposed to our moral principles, and the repetition of harmless melodies and verses prevents thoughts on topics which we have been taught to taboo. The repetition of the obsessional act or thought varies in intensity and becomes more incessant as the outlaw idea approaches the surface of consciousness and threatens to break forth. Like many another evil in life, in the case of obsessions, it is often better to bear the ills we have than to fly to others in the subconscious mind for which they stand as symbols.

We have referred previously to the thought-tight compartments into which the mind may be divided. This mechanism, too, serves a conservative purpose in everyday life, and its use is a common and perhaps inevitable occurrence in the psychological life of every human being. The reason for this is that our political and religious beliefs and the traditions of our childhood are notoriously inaccessible to argument and we stick to them in spite of evidence that refutes them every day. Such a contradictory state of affairs can only be explained by assuming the existence of a certain amount of dissociation which splits these systems of belief off from the rest of the mind and leaves them high and dry like desert islands in the midst of the stream of consciousness. The solvent action of the tide of unbiased and freely moving flood of thought that surrounds these islands has no effect on their rock-ribbed shores. That paradoxical definition of the word faith as "belief in what we know is not true" finds here its apotheosis. It needs no faith to believe in things of which our senses give us proof or which the mind can determine by a logical process of reasoning. But we hold to religious and political ideas which our grown-up intelligence knows are not true, simply because it is safer for our peace of mind and because we dare not risk the upheaval that would ensue should we attempt to dig about the roots that grew so strong and deep in childhood and adolescence.

## THE TREATMENT OF HEMORRHAGE IN PEPTIC ULCER\*

By WALTER A. BASTEDO, MD, NEW YORK, N Y

**B**LEEDING from a peptic ulcer may be  
1 The slight ooze which appears merely as occult blood in the stools. This usually ceases in a few days under the accepted methods for the medical management of ulcer.

2 The larger hemorrhage which shows grossly in the stool but is not enough to produce obvious symptoms of hemorrhage. This is usually also satisfactorily treated by ordinary ulcer management, though an arbitrary period of three days without food or water by mouth is usually considered advisable, as well as the administration of a coagulant.

3 The profuse hemorrhage which is accompanied by weakness, fainting, air hunger and anemia.

4 The continuous or frequently recurrent small hemorrhage that gradually brings on a marked secondary anemia.

Whether the ulcer is duodenal or gastric does not alter the medical treatment for hemorrhage. The therapeutic desiderata are 1 to stop the bleeding, 2 to overcome the effects of loss of

blood, and 3 to forestall and prevent recurrence of the hemorrhage.

In hemorrhage compensation mechanisms are set to work promptly. To stop the bleeding the ruptured arteriole retracts and contracts and the blood clots at its mouth. To maintain the blood volume there is absorption of tissue fluid, of lymph and of water from the alimentary tract. To maintain the blood pressure the vasoconstrictor center causes active constriction of arterioles generally in the body, or at least in the splanchnic area. As the cerebral arteries and the cardiac coronary arteries are not controlled by the vasoconstrictor center, these do not contract and will continue to furnish blood to the brain and heart even though the general arterial system is in constriction. This is a necessary provision for the maintenance of life. Wiggers has shown that after hemorrhage the coronary flow equals or exceeds the normal flow even though the systemic arterial pressure is below normal. There is, therefore, no reason for the administration of heart stimulants, and there is contraindication to any drug, such as nitroglycerin, to overcome the general peripheral constriction.

\* Read before the Medical Society of the County of New York October 25, 1926.

*The local situation.* Retraction and contraction of the bleeding vessel, together with clotting being the local desiderata, it is to be remembered that we are dealing not with normal tissue, but with ulcer tissue. In a very recent ulcer the connective tissue formation is little, so that the bleeding vessel may retract and clotting take place readily. Hence, in the acute ulcer, hemorrhage, if not massive, is prone to shut itself off quickly. In the indurated ulcer on the other hand, bleeding may persist or recur with greater ease. Clotting takes several minutes, and because of the pressure of the flowing blood does not begin at the mouth of the bleeding vessel but at some distance from it, reaching back by accretion till it stops the mouth of the vessel. Therefore the more the tissues interfere with the free flow of blood, the more readily does the clot form and the bleeding stop. Hence for clotting, the favorable condition is an empty contracted viscus with the mucous membrane in deep folds. But peristaltic activity should be avoided, for not only does it interfere with the normal accretion of the clot, but it may loosen a clot already formed. Anything that will induce sudden access of blood pressure may do likewise. In other words, to favor and maintain effective clot formation we need a quiet contracted stomach, quiet heart, quiet respiration and avoidance of vomiting.

*Lavage.* If the stomach is not contracted, lavage is indicated. As said by Arpad Gerster "A bleeding hollow organ distended by coagulated blood will not cease bleeding until that clot is evacuated." Kaufmann reports a case with stomach distended with blood and gas, and pulse of 170 relieved by lavage. Lavage may stop a continuous bleeding by removing a partial and ineffective clot and permitting the formation of an effective one. The chief object, however, is to empty the stomach and so permit the viscus to contract. The use of very cold or very hot water to stop the bleeding is probably of no advantage in such a large area, and may have the disadvantage of arousing peristalsis. If desired, the lavage may be followed by the introduction through a tube, of remedies to act locally. C. R. Jones introduces an ounce or two of gelatin of syrupy consistency containing ten minims of solution of adrenalin. Many have used a coagulant such as thromboplastin. This introduction of remedies is sub judice because of its problematic usefulness and because anything introduced into the stomach may induce peristalsis.

Lavage is not necessary if the stomach is already contracted, and if the bleeding has stopped may do harm by loosening the clot. It is contraindicated if there is evidence of portal congestion. For who can tell that the bleeding is surely from an ulcer and not from the varicose veins of the lower esophagus which in cirrhosis of the

liver or portal thrombosis are so often the site of hemorrhage.

*Morphine.* To lessen the patient's excitability, to lower the accompanying acceleration of the heart and respiration, and to decrease peristalsis and the tendency to vomiting, there is no better remedy than a hypodermic of morphine. But morphine has the striking disadvantage that while it abolishes peristalsis it also abolishes tone, so that in large doses it may produce an atonic dilatation, a state just the opposite of that desired. To counteract this tendency I would accompany the morphine with a maximum dose of strychnine, which, while it does not initiate peristaltic movements, has the power to increase tone. Strychnine does not appreciably counteract the desired effects of morphine on the brain and the respiratory and vagus centers. Atropine is not desirable as it does not counteract the relaxing effect of morphine, and it annuls the vagus control of the heart.

*Coagulants.* Though it has been shown that hemorrhage may itself result in increased blood coagulability, this occurs only to a moderate degree, and then only from very rapid or massive hemorrhages. Therefore it is advisable to use coagulants for their systemic effect. It is to be borne in mind that in the usual ulcer case the blood has normal coagulability, therefore the use of coagulants systemically is solely for the purpose of hastening the coagulation time beyond the normal.

When one of these coagulants is applied locally it acts to favor clot formation at the site of injury, but if it is administered to the body it reduces the coagulation time of the whole blood in the body. In experimental work on animals the blood has been brought by some of these agents administered intravenously from a coagulation time of 8 or 9 minutes to one of 1 or 2 minutes. The effect is less from the subcutaneous or intramuscular administration, but is still distinct, and is seen even from mouth doses. If in sufficient quantity a coagulant will produce intravascular clotting, a consummation devoutly not to be wished for, but this occurs only with intravenous doses and the danger is not present when the drugs are used by mouth or hypodermatically.

The coagulant substances available are cephalin, thromboplastin, coagulen, blood serum and its precipitated derivative coagulose, homostatic serum, whole blood and sodium citrate.

Cephalin and thromboplastin are liquid lipid preparations made from brain tissue. Coagulen is a powdery preparation of the blood platelets. They all contain the physiological substance known as cephalin or thrombokinasin. From their intravenous administration the action begins in about half an hour, reaches its maximum in about  $1\frac{1}{2}$  to 2 hours, and lasts about 4 to 6 hours. From subcutaneous doses the action may

appear almost as quickly, but as a rule its appearance may be retarded for several hours or even twelve hours or more. Therefore coagulants are scarcely emergency remedies.

*Blood serum*, as it is the liquid squeezed out from a clot, is lacking all the elements removed in the clot, nevertheless it has the property of increasing the coagulability of the blood. It loses this property quickly, the loss during the first hour being quite rapid, and after that progressively slower. The loss may be retarded by keeping it in an ice-chest or, as Mills discovered, by adding to the serum enough solid sodium chloride to make a 6 per cent solution. Old stock horse serum administered intravenously in large quantities, for example in pneumonia, has no marked effect on the coagulability of the blood. Fresh serum, however, of the human being, rabbit, sheep and horse may be employed, the rabbit's serum being the most potent. According to Clowes and Busch human serum is in no wise superior in clotting power to that of the animals mentioned, yet, being homologous, it may be employed in much larger quantity.

It is well to note that old serum may be reactivated by the addition of weak alkalis or weak acids, and may become especially active on the addition of cephalin or thromboplastin. Indeed Mills found that old horse serum if introduced intravenously within two or three minutes of reactivation by fresh physiological cephalin, would produce intravascular clotting.

The great disadvantage in the use of serums in the large quantities necessary is the serum sickness which so frequently follows a week or two later. But they may be administered intravenously without the risk of intravascular clotting. In their intravenous use of course, the usual tests should be made to avoid anaphylactic shock. The dose usually employed is 20 c.c. subcutaneously, repeated every 12 hours, but taken all in all, serum is not of great value.

Diphtheria antitoxin, though prepared from horse serum, has practically no effect on coagulability. It is refined to a very high protein content, and this protein consists almost entirely of pseudoglobulins which have little value as coagulants.

*Hemostatic serum*, a proprietary preparation, is claimed to be a very concentrated serum, which contains cephalin or thrombokinase, pro-thrombin and anti-thrombin. The claim is made that it retains its potency unusually long. It is standardized by the requirement that 2 c.c. administered intravenously to a 12 kilo dog, shortens the coagulation time to at least one-third the normal. As canine and human clotting correspond in every way, this would represent an intravenous dose for a 70 kilo human of 12 c.c. and would seem to permit the intravenous use in great emergency of 2 c.c. Its subcutaneous or intramus-

cular dose in the ordinary case is 2 c.c. and in the severe case 5 c.c. It should be diluted with normal saline and repeated every 4 to 6 hours. The small dose necessary avoids the subsequent serum sickness, but if used intravenously, the usual anaphylaxis precautions should be taken. It is a preparation that will bear further scientific investigation.

*Whole blood* in massive amounts as in transfusion has double value, for it restores the blood volume and also improves its clotting power. Subcutaneously whole blood has the disadvantage that it may form merely a hematoma which is absorbed very slowly.

*Sodium citrate* in 30 per cent solution in dose of 15 c.c. in each buttock produces a prompt decrease in the coagulation time, lasting one to three hours with gradual return to normal. This is in striking contrast with its power to check coagulability when added to blood in vitro.

*Calcium*. In internal hemorrhages in ordinary cases (not jaundiced) calcium salts have no value, and an increase in the calcium ions in the blood beyond the physiological point may result in decreased coagulability (Lapenta).

*Measures to restore the blood volume*. For this there is nothing that compares with transfusion, therefore in profuse hemorrhage the patient should at once be grouped so that transfusion may be performed without delay if it is deemed necessary. The fear that the addition of a quantity of blood to the circulation may induce renewed hemorrhage need not be entertained. In spite of Ottenberg and Libman's warning against transfusion in first hemorrhages, I should say with Bernheim, "When in doubt, transfuse." But I should not adopt Bernheim's rule to wait for transfusion till the systolic pressure drops to 70, nor would I be guided wholly by the hemoglobin. For owing to the action of the vasoconstrictors, to the natural elasticity of the larger arteries and to the usual acceleration of the heart's rate, the blood-pressure may be maintained for a time though the total volume of blood is progressively falling. Likewise the hemoglobin drops only as the blood becomes diluted by the tissue fluids, lymph, etc., and the patient may need blood even if that which he has does not show a very low hemoglobin. Therefore I should transfuse anyway if the hemorrhage seems to be continuous or recurs in large volume, or if the patient shows symptoms of blood loss.

In great emergency where transfusion is not available, salt solution, preferably of Ringer's or Locke's formula, may be introduced by rectum, by hypodermoclysis or intravenously. Salines do not change the coagulability of the blood, and they may maintain the blood volume for a sufficient length of time to save the patient's life. Hypertonic glucose solutions have also been suggested.

*Measures to increase the blood's viscosity*, such as the addition of gelatin or acacia to the saline, give very little promise of help and have disadvantages

*Mechanical Measures* The patient should, of course, be in bed and kept warm. In case of exsanguination one can bandage the limbs and raise the foot of the bed high, or even bandage the abdomen and place weights upon it as suggested by Meltzer, for it is necessary to maintain the cerebral and coronary circulations at all costs or the patient will die.

The use of an ice-bag over the stomach is customary, but physiological experiments give no justification for its employment.

*Surgery* It is the consensus of opinion that while surgery may be called for in recurrent hemorrhages, immediate surgery is contraindicated in the presence of a profuse hemorrhage. It has been estimated by Moynihan that not over 3 per cent of profusely bleeding gastric or duodenal ulcers could be treated successfully by laparotomy. As a matter of fact, either spontaneously or because of, or in spite of medical measures employed, nearly all hemorrhages cease and are not fatal. So that by the time we have decided that the hemorrhage is not going to cease the patient is beyond the point of safety for an operation. Moreover it is a risky operation, and in the presence of so much blood it is often impossible to locate the bleeding spot.

Lindberg, of Faber's clinic in Copenhagen, tabulated 68 cases so severe as to raise the question of an emergency operation. It was decided in all the cases to give medical treatment. Only five died, and the autopsies showed that not one of the five could have been helped by surgery. These statistics, together with unfavorable statistics from other clinics where operation had been performed, convinced Lindberg that surgical measures are never indicated in acute hemorrhage from the stomach or adjacent bowel. The experience of most surgeons would tally with that of Lund who remarked "I have learned that it is poor practice, when the patient is depleted by hemorrhage, to open the stomach and try to grasp the artery in the bottom of an ulcer."

*In the cases with continued or repeated slight bleeding sufficient to produce a decided anemia*, there is a reduction of the fibrinogen and prothrombin content of the plasma and excess production of antithrombin. Consequently the failure of the bleeding to cease may be due to the formation of a loose and inefficient clot. In such a case the treatment is transfusion followed at a convenient period by surgery.

When the measures mentioned below are unavailing and bleeding persists, as shown by repeated vomiting of fresh blood or profuse bloody

diarrhea, it is unjustifiable to stand around and watch the patient slowly die. In such case I would advocate surgery following transfusion. I recall one such case saved by operation, in which the surgeon found a vein eroded on one side and held open because it could not retract.

### SUMMARY

#### *The Treatment in Severe Hemorrhage* is

1 Have the patient very quiet, lying down with head low, with plenty of fresh air and with body kept warm.

2 If there is severe exsanguination, bandage legs and arms, raise the foot of the bed and bandage and put weights on the abdomen.

3 Avoid unnecessary manipulation of the abdomen.

4 Give a hypodermic of morphine sulphate, 0.015 gram (gr  $\frac{1}{4}$ ) with strychnine sulphate 0.002 to 0.003 gram (gr  $\frac{1}{30}$  to  $\frac{1}{20}$ ).

5 Administer hypodermically every six to twelve hours 20 cc of fresh rabbit or horse serum, 2 cc of hemostatic serum or 10 cc of thromboplastin.

6 Prepare early for transfusion and as soon as there are indications for it transfuse.

7 If there is exsanguination to the danger point and transfusion cannot be done give intravenously Locke's or Ringer's solution, normal saline or 20 per cent glucose, and give normal saline by rectum or by hypodermoclysis.

8 If the stomach remains distended and the bleeding seems to persist, lavage with tepid water and follow this by passing in through the tube a solution of thromboplastin, kephalin or coagulen, or gelatin with epinephrin. In portal congestion cases or if apparently the bleeding has ceased, avoid lavage.

*When these measures are unavailing, and dangerous bleeding persists*, as shown by repeated vomiting of fresh blood or profuse bloody diarrhea, resort to surgery.

*In cases with continued or repeated slow bleeding sufficient to produce a decided anemia* but without immediate danger to life, the failure of medical measures calls for surgery.

*The Subsequent Treatment* is 1 Avoid putting anything at all in the stomach for three days, giving saline by rectum every six hours to allay thirst.

2 Give a soapsuds enema once a day.

3 At the end of three days give milk of magnesia sufficient to clean out all remaining blood from the bowels, for blood in the bowel putrefies quickly.

4 Then begin the regular medical treatment of ulcer.

5 Have patient use the bed-pan for several days after the hemorrhage, and then a commode by the bed.

appear almost as quickly, but as a rule its appearance may be retarded for several hours or even twelve hours or more. Therefore coagulants are scarcely emergency remedies.

*Blood serum*, as it is the liquid squeezed out from a clot, is lacking all the elements removed in the clot, nevertheless it has the property of increasing the coagulability of the blood. It loses this property quickly, the loss during the first hour being quite rapid, and after that progressively slower. The loss may be retarded by keeping it in an ice-chest or, as Mills discovered, by adding to the serum enough solid sodium chloride to make a 6 per cent solution. Old stock horse serum administered intravenously in large quantities, for example in pneumonia, has no marked effect on the coagulability of the blood. Fresh serum however, of the human being, rabbit, sheep and horse may be employed, the rabbit's serum being the most potent. According to Clowes and Busch human serum is in no wise superior in clotting power to that of the animals mentioned, yet, being homologous, it may be employed in much larger quantity.

It is well to note that old serum may be reactivated by the addition of weak alkalis or weak acids, and may become especially active on the addition of cephalin or thromboplastin. Indeed Mills found that old horse serum if introduced intravenously within two or three minutes of reactivation by fresh physiological cephalin, would produce intravascular clotting.

The great disadvantage in the use of serums in the large quantities necessary is the serum sickness which so frequently follows a week or two later. But they may be administered intravenously without the risk of intravascular clotting. In their intravenous use of course, the usual tests should be made to avoid anaphylactic shock. The dose usually employed is 20 c.c. subcutaneously, repeated every 12 hours, but taken all in all, serum is not of great value.

Diphtheria antitoxin, though prepared from horse serum, has practically no effect on coagulability. It is refined to a very high protein content, and this protein consists almost entirely of pseudoglobulins which have little value as coagulants.

*Hemostatic serum*, a proprietary preparation, is claimed to be a very concentrated serum, which contains cephalin or thrombokinas, pro-thrombin and anti-thrombin. The claim is made that it retains its potency unusually long. It is standardized by the requirement that 2 c.c. administered intravenously to a 12 kilo dog, shortens the coagulation time to at least one-third the normal. As canine and human clotting correspond in every way, this would represent an intravenous dose for a 70 kilo human of 12 c.c. and would seem to permit the intravenous use in great emergency of 2 c.c. Its subcutaneous or intramus-

cular dose in the ordinary case is 2 c.c. and in the severe case 5 c.c. It should be diluted with normal saline and repeated every 4 to 6 hours. The small dose necessary avoids the subsequent serum sickness, but if used intravenously, the usual anaphylaxis precautions should be taken. It is a preparation that will bear further scientific investigation.

*Whole blood* in massive amounts as in transfusion has double value, for it restores the blood volume and also improves its clotting power. Subcutaneously whole blood has the disadvantage that it may form merely a hematoma which is absorbed very slowly.

*Sodium citrate* in 30 per cent solution in dose of 15 c.c. in each buttock produces a prompt decrease in the coagulation time, lasting one to three hours with gradual return to normal. This is in striking contrast with its power to check coagulability when added to blood *in vitro*.

*Calcium*. In internal hemorrhages in ordinary cases (not jaundiced) calcium salts have no value, and an increase in the calcium ions in the blood beyond the physiological point may result in decreased coagulability (Lapenta).

*Measures to restore the blood volume*. For this there is nothing that compares with transfusion, therefore in profuse hemorrhage the patient should at once be grouped so that transfusion may be performed without delay if it is deemed necessary. The fear that the addition of a quantity of blood to the circulation may induce renewed hemorrhage need not be entertained. In spite of Ottenberg and Libman's warning against transfusion in first hemorrhages, I should say with Bernheim, "When in doubt transfuse." But I should not adopt Bernheim's rule to wait for transfusion till the systolic pressure drops to 70, nor would I be guided wholly by the hemoglobin. For owing to the action of the vasoconstrictors, to the natural elasticity of the larger arteries and to the usual acceleration of the heart's rate, the blood-pressure may be maintained for a time though the total volume of blood is progressively falling. Likewise the hemoglobin drops only as the blood becomes diluted by the tissue fluids, lymph, etc., and the patient may need blood even if that which he has does not show a very low hemoglobin. Therefore I should transfuse anyway if the hemorrhage seems to be continuous or recurs in large volume, or if the patient shows symptoms of blood loss.

In great emergency where transfusion is not available, salt solution, preferably of Ringer's or Locke's formula, may be introduced by rectum, by hypodermoclysis or intravenously. Salines do not change the coagulability of the blood, and they may maintain the blood volume for a sufficient length of time to save the patient's life. Hypertonic glucose solutions have also been suggested.

ment throughout the country. Many patients suffering from this dilatation of the bronchial walls have been diagnosed anything from tuberculosis, lung abscess, lues, fistulas, etc. The symptoms are often vague and the history generally dates back over a long period when, following a cold in the chest, a resultant condition of cough and drainage of a large amount of foul smelling secretion is noted. This usually comes up about once a day, at nearly the same hour, followed by relief.

The method followed is to cocaine the throat, insert the bronchoscope and aspirate the secretions, followed either by irrigation or the injection of 20 per cent Gomenol. The patients leave the table and go home, many improving after the first treatment. This procedure is usually repeated at weekly intervals. The odor generally disappears immediately, the cough decreases and the amount of secretion lessens. In cases that the internists desire vaccine treatments, a specimen is taken directly from the cavity for culture. The use of lipiodol is a valuable diagnostic and therapeutic aid.

#### DIAGNOSIS OF DISEASE

In cases of new growths direct vision tells us of the size and the condition of the surrounding structures and at the same time a section can be removed for examination. Strictures can be dilated or incised, diverticulae discovered and in cases of spasm a dilating tube can be inserted and relief obtained. To the surgeon performing gastrostomies, retrograde esophagoscopy is most valuable. Lately Moore of Philadelphia is diagnosing and treating bronchial asthma and pulmonary oedema with the bronchoscope.

#### CASE REPORTS

To illustrate a few of the above mentioned conditions, the following case histories are reported.

1 Girl, age 11, cough lasting nearly a year, expectoration and loss of weight. Prepared for Saranac Lake with a diagnosis of tuberculosis. During a bad coughing spell late at night the regular family physician could not be reached and a neighborhood recent graduate was called. An X-ray was requested and the following day the writer removed a red octangular glass bead. Child now well.

2 Baby, 13 months old, suddenly started to cry and vomit. Family doctor ordered sedatives, but obtained no relief. A second and third were called with the same result. A fourth ordered an X-ray and within two hours of this we removed an open safety pin from the larynx.

3 Boy, age five, treated for pneumonia for

over a week. Peanut removed right bronchus on eighth day.

4 Boy, age 17, had pneumonia six months previous, followed by cough, loss of weight, expectoration of a couple of cups of foul smelling pus daily. After five aspirations and injections, his weight increased, odor disappeared and secretions nil.

5 Boy, age 10, was operated on two years previous for removal of tonsils and adenoids under ether anesthesia. Developed what was considered bronchopneumonia and on the failure of the chest to clear up, a diagnosis of tuberculosis was made and the child was sent to an institution for the chest condition. At the yearly change of hospital internes, the coming interne ordered another series of chest plates. A suspicious shadow called for a bronchoscopy which was performed under nitrous oxide anesthesia. A large lung abscess was drained. This was repeated three times and the fourth operation revealed a mass of granulated tissue filling the left bronchus, which was removed and beyond this mass a piece of rubber tubing from the original tonsil operation was removed. Child gained immediately.

6 Baby, age 12 months, coughing for 11 weeks. Physician told mother child could not have a foreign body because it did not cough out any blood. Child's condition grew progressively worse and a diagnosis of pneumonia was made. A consultation called for an X-ray. Plate showed an open safety pin lodged in right bronchus with the lung pneumonic. The child by this time was in poor condition. A low tracheotomy was performed but attempts to remove the pin were to no avail, as it was so firmly wedged in the mass of new formed connective tissue. Patient died from cardiac failure.

7 Man, age 80, difficulty in swallowing and much cough with secretion. Diagnosis chronic bronchitis, gastritis. Without anesthesia a scope was passed and a large ulcerating carcinoma was found.

#### CONCLUSION

The foregoing paper is offered more to the physicians in the field of general medicine rather than to present the same features to a group of men specializing in endoscopy, as the burden of early recognition, which is primarily the keynote of a successful bronchoscopic result, hangs on the shoulders of the general practitioner, as he is generally the first called upon to make a diagnosis and after arriving at his conclusions, he is looked upon as the judge as to what course is to be followed. Cooperation between the endoscopist and the private physician is the ideal to be realized.

# NEWER METHODS IN BRONCHOSCOPY AND ESOPHAGOSCOPY, WITH SPECIAL REFERENCE TO THE GENERAL PRACTITIONER

By MORRIS E. NEWMAN, M.D., BUFFALO, N. Y.

**D**URING the last few years the science of medicine has observed marked changes in the field of bronchoscopy and esophagoscopy, so that now the principles, originally perfected for the removal of foreign bodies in the air and food passages, have greatly increased their scope of usefulness. Many important contributions have been added in the diagnosis and treatment of diseases of these tracts, so that today the foreign body angle constitutes but a small part of the endoscopist's work. Blind methods of diagnosis and treatment are being replaced by the more scientific methods of direct inspection.

It is not the purpose of this paper to describe the technic of introducing the instruments or the details of such operations, but to call attention to the various diagnostic uses and their appliance, as would interest the physician doing general practice.

For brevity, I shall divide this paper into sections, viz (1) Foreign bodies in the air and food tracts, (2) Lung suppurations, (3) Diagnosis of disease.

## FOREIGN BODIES

These are more common than are generally recognized. Many children have been treated for various ailments when a foreign body was the seat of the trouble. With a definite history of playing with some foreign object, cough and choking, there is little difficulty in making a diagnosis. However, so often a history is lacking and the symptoms so vague that many of these cases are overlooked. The symptoms and physical signs vary with the position, size, shape and character of the foreign body and often vary from hour to hour. Objects of vegetable origin produce more severe symptoms, especially in children. Some time ago I reported six peanut cases in the bronchi of children, three of these were being treated over a period of time for pneumonia. The danger present in this class of case is the oil contained therein, which produces by its irritation a drowned lung. Early removal ordinarily saves these children. Although X-ray examinations are invaluable in opaque foreign bodies, it is possible by careful study of the changes in the lung and surrounding structures to localize non-opaque, foreign objects. Cases of long duration are often confused with pulmonary tuberculosis and bronchiectasis. They must be differentiated from neoplasms, enlarged mediastinal glands and aneurysm.

Every foreign body must be removed. Spontaneous expulsion occurs in only a few cases, probably less than three per cent. Inverting the

patient has its dangers, because of the possibility of forcing the object into the glottis. No one should attempt to remove a foreign body without proper instruments and training. The old fashioned way of pushing the finger down the throat should be discouraged. The high points in summarizing this group then are: History, sudden cough and shortness of breath, wheeze, physical signs and X-ray.

In referring to foreign bodies in the food tract a different problem is found, as here we have an outlet for the object to pass through. Those objects whose contour or size prevent passing through, such as pins, large coins or bones, should be removed under local anesthesia. Perforations of the esophagus are not rare and are generally fatal. One of the more common esophageal conditions, both the family physician and specialist are called upon to treat, is stricture. The crude methods some chemical manufacturers use to mark their lye cans have been the cause of a large number of cases of lye burns of the alimentary tract. These cases are serious and their final outcome depends on the degree of the burn and the period of time given to treatments to overcome the stenosis.

It is evident from the above that the foreign body problem is to be considered as a distinct entity in practice.

## LUNG SUPPURATIONS

*Lung Abscess*—These may follow surgical operations, trauma, pneumonia or secondary to infections elsewhere and carried by the blood stream. In these cases bronchoscopy is recognized as a useful aid in the diagnosis and localization of foci and a valuable help in its treatment. Cases, where there is a communication to the bronchial lumen, are tubed and the contents then aspirated, and followed by medication directly into the cavity. In those cases in which masses of granulation tissues or constriction are present to impede drainage, surgical means are instituted through the tube.

Among the more recent advances in these types of case is the injection of a solution called lipiodol through the bronchoscope into the bronchial tree. This is a solution containing forty per cent of iodine. This suspended solution travels to all parts of the tree and its opaque shadows, as shown by the X-ray plates and screen, are a great aid in diagnosis and an indicator for further surgical procedures. The iodine therein contained is thought to have therapeutic value.

*Bronchiectasis*—There has been considerable research work carried on in this bronchial ail

age never having walked or talked. The Wassermann test of the cerebrospinal fluid was positive in only 0.5 per cent of all the cases (i.e. one in 200 cases).

Having in mind these 59 extreme acute cases and also these 671 chronic cases of cerebral birth hemorrhage, the possible frequency of acute intracranial hemorrhage in the newborn was considered to a degree that a lumbar puncture within from twelve to twenty-four hours after birth was advised in a test series of 500 consecutive newborn babies as a routine procedure and irrespective of the type of labor. It is true that babies having large intracranial hemorrhage frequently did disclose signs of its presence by varying degrees of stupor, respiratory difficulties, refusal to nurse and muscular twitchings even to convulsive seizures, and at necropsy the diagnosis was confirmed (it being considered fortunate that the baby did not survive). In the milder degrees of intracranial hemorrhage of an amount that could be entirely absorbed together with the cerebrospinal fluid by the natural means of absorption alone, then the acute signs, if any, of its presence were of such temporary duration, of several days at most, that the child made a permanent excellent recovery, and the birth history was quickly forgotten, if indeed anything abnormal at the time of birth had been observed. However, in those cases in which the amount of intracranial hemorrhage was not of sufficient degree to cause death and yet of larger quantity than could be entirely absorbed by the natural means of absorption (through the walls of the supracortical veins chiefly (80 per cent), sinuses, pachionian bodies, etc.), the babies only apparently recovered from the acute condition within a period of from two to four weeks and were even considered normal until the seventh month and usually within the first year when it was noticed that the child was not developing physically at the normal rate as to holding up its head and sitting up, and later was retarded in beginning to walk and to talk. Usually within the latter part of the first year an increasing spasticity of either one or both legs appeared as part of a hemiplegic or a diplegic condition. It is in the latter chronic conditions of intracranial hemorrhage in the newborn that the etiologic factor of hemorrhage has been frequently overlooked owing to the paucity and even lack of the clinical signs at the time of the acute condition at birth—the cells of the cerebral cortex being only partially developed at the time of birth and thus even large cerebral lesions not being disclosed clinically. Then the later development of a chronic physical and mental impairment in a child apparently normal up to the latter part of the first year has been a most puzzling one, the factors of heredity, alcoholism, lues, etc., being most frequently considered. These observations regarding the character of the cerebrospinal fluid were made in the hope that the acute

condition of intracranial hemorrhage in the newborn will be more frequently recognized, so that its appropriate treatment—possible repeated lumbar punctures of spinal drainage together with the methods of increasing the blood coagulability—may be instituted early, while the blood is in fluid form and not after a period of days, when the hemorrhage that may not be absorbed has coagulated. Thus the hope that the permanent presence of a supra-cortical organization-residue—the future obstruction to free absorption of the cerebrospinal fluid and the underlying cause of varying degrees of increased intracranial pressure of cerebral edema in these chronic cases of cerebral spastic paralysis, can be prevented.

A brief summary of the series of 500 consecutive newborn babies on whom a lumbar puncture was performed within from twelve to twenty-four hours after birth, by my associates, Doctors A. S. MacLaire<sup>29</sup> and G. E. Espejo<sup>30</sup> and through the courtesy of Doctors Child, Dorman and Ward at the City Hospital, Welfare Island, is as follows. In forty-five babies there was disclosed bloody and blood-tinged cerebrospinal fluid, that is, in 9 per cent of the entire series. One other baby dying before a lumbar puncture was performed—the puncture being made fifteen minutes after death—revealed at necropsy an extensive intracranial hemorrhage with bloody spinal fluid, this case however has not been included as having bloody cerebrospinal fluid. In as many as fifty babies, that is, 10 per cent of the entire series, no lumbar puncture was performed—in thirty-six a dry tap was recorded, and in fourteen the test was not performed, as seven babies were in severe shock and seven premature babies were in poor condition.

In making the test of lumbar puncture in this series, if bloody, blood-tinged or yellow and straw-colored cerebrospinal fluid was disclosed, then another immediate confirmatory puncture was made one interspace higher—merely to prove or disprove the presence of blood in the first test. In the bloody cases, another test was made within a period of twenty-four hours, and cerebrospinal fluid was drained of an amount not to lower the pressure below the normal 4 to 6 mm of mercury. These daily tests were repeated until the fluid became clear and under normal pressure. As many as seven punctures of drainage were necessary in several cases, and yet the average number was slightly over three.

There were three deaths in this series of newborn babies on whom a lumbar puncture revealed blood in the cerebrospinal fluid—two in the first hundred and one in the fourth hundred. Post-mortem examinations disclosed a large ventricular hemorrhage in the first, extensive supracortical hemorrhage and cerebral edema in the second, and large supracortical, basal, subtentorial and spinal hemorrhage in the third baby. Their com-

# OBSERVATIONS REGARDING INTRACRANIAL HEMORRHAGE IN THE NEWBORN\*

By WILLIAM SHARPE, MD, NEW YORK CITY

UNTIL recent years the literature of intracranial hemorrhage in the newborn has been concerned with the extreme cases, either as post mortem studies of extensive intracranial hemorrhage due to laceration of the large sinuses, tentorium, falx, etc., or as clinical observations of the signs of a probable large intracranial lesion or hemorrhage, (general convulsive seizures, profound stupor, etc.), and the description of methods to increase the coagulability of the blood and in this manner lessen the cerebral damage and its possible resulting chronic condition of cerebral spastic paralysis with mental retardation. Almost 100 years ago, Denis,<sup>1</sup> Billard,<sup>2</sup> and Cruveilhier,<sup>3</sup> in the period from 1826 to 1835, published several papers intimating and suggesting the causal relationship of intracranial hemorrhage at birth and the later development of cerebral spastic paralysis. In 1843, Little<sup>4</sup> of London stated in his first monograph on the subject of "Deformities of the Human Frame" that a difficult labor might be an etiologic factor, but that a lack of development of cerebral tissues and meningitic inflammatory processes were the usual causes. Only nineteen years later (1862), in his second monograph<sup>5</sup> on this subject, Little stated that, as a result of further study, especially of a large series of post-mortem examinations, he was of the opinion that almost 75% of the cases of cerebral spastic paralysis were due to an intracranial hemorrhage at the time of birth. In 1885, Sarah McNutt confirmed this opinion by careful pathologic studies. More recently, Beneke<sup>6</sup> in 1910, Pott<sup>7</sup> in 1911, Mayer<sup>8</sup> in 1915, Holland<sup>9</sup> in 1920, and within the last four years Schafer,<sup>10</sup> Schwartz,<sup>11</sup> Saenger,<sup>12</sup> Capon,<sup>13</sup> Barnett<sup>14</sup> and others have contributed valuable postmortem observations, and yet the literature of the clinical observations has been most meagre. In this country Green,<sup>15</sup> Brady,<sup>16</sup> Sidbury,<sup>17</sup> Warwick,<sup>18</sup> Rodda,<sup>19</sup> Strauchauer,<sup>20</sup> Ehrenfest,<sup>21</sup> Conkey,<sup>22</sup> Huenekens,<sup>23</sup> and Monroe and Eustis,<sup>24</sup> have all added to the knowledge of the subject during the last decade. In 1924 Schwartz,<sup>25</sup> of Berlin stated that "the pathology of the first month of life is completely dominated by the birth injuries of the brain", Fisher<sup>26</sup> of Basel wrote in 1924 that his postmortem observations at the Institute had convinced him that "the 10 per cent of deaths during the first month are chiefly due to cerebral birth injuries", and Huenekens,<sup>27</sup> in an article in 1919, stated that "the recognition of cerebral hemorrhage of the newborn is a most neglected phase in their care and yet it is a most important one."

During the last twelve years (up to January 1925), 59 acute cases of extensive intracranial hemorrhage in the newborn<sup>28</sup> (the accuracy of the diagnosis being confirmed by lumbar puncture, cranial operation and necropsy) have been studied in my clinic—the most common signs being profound stupor, refusal to nurse and muscular twitchings, and during the same period of 12 years, 671 chronic cases in children with varying degrees of spastic paralysis and mental retardations have been examined and in whom, in selected cases having a marked increase of the intracranial pressure, the diagnosis of a former intracranial hemorrhage, most probably occurring at the time of birth, was confirmed by operative and postmortem findings, the histories of the labor and the first week after birth of these 671 chronic cases of cerebral spastic paralysis, with or without marked mental retardation, with the subsequent operative and post mortem findings of a supracortical hemorrhagic organization residue producing a partial blockage of the excretion of the cerebrospinal fluid and thus the increased intracranial pressure of chronic cerebral edema, have been most instructive, 81 per cent were first children, 72 per cent, were boys, 95 per cent were full term babies, in 90 per cent, the labor was prolonged and difficult, forceps having been applied in 76 per cent of them, although in a large percentage of these cases, more as a last resort than as an early indication, in 17 per cent the presentation was a breech. Pituitary extract was recorded as having been used in 8 per cent of these cases. During the first week after birth, 64 per cent of these children were considered more drowsy and stuporous than is normal, 23 per cent refused to nurse and 78 per cent did not evince the normal demand for food, 39 per cent had muscular twitchings of varying degree, particularly of the orbital muscles and of either leg or hand, in 17 per cent general convulsive seizures occurred one or more times during the first two weeks. An icteroid appearance was noted in 18 per cent. Within two weeks after birth, 61 per cent of these children were so called "well" and "normal" (if anything serious had been suspected at all), and in 82 per cent of them, at one month after birth, the child was "to all appearances" normal in every way. With the exception of 21 per cent, it was only in the later months of the first year that it was observed that the child was not beginning to hold up its head and to sit up when it normally should do so and in 79 per cent, the beginning of spasticity of the legs or arms was not demonstrable before the seventh month. The later history of not walking and talking within the normal age limits varied by months and even years, a small percent-

\*Presented at the First District Branch of the Medical Society of the State of New York, November 19, 1926.

age never having walked or talked. The Wassermann test of the cerebrospinal fluid was positive in only 0.5 per cent of all the cases (i.e. one in 200 cases).

Having in mind these 59 extreme acute cases and also these 671 chronic cases of cerebral birth hemorrhage, the possible frequency of acute intracranial hemorrhage in the newborn was considered to a degree that a lumbar puncture within from twelve to twenty-four hours after birth was advised in a test series of 500 consecutive newborn babies as a routine procedure and irrespective of the type of labor. It is true that babies having large intracranial hemorrhage frequently did disclose signs of its presence by varying degrees of stupor, respiratory difficulties, refusal to nurse and muscular twitchings even to convulsive seizures, and at necropsy the diagnosis was confirmed (it being considered fortunate that the baby did not survive). In the milder degrees of intracranial hemorrhage of an amount that could be entirely absorbed together with the cerebrospinal fluid by the natural means of absorption alone, then the acute signs, if any, of its presence were of such temporary duration, of several days at most, that the child made a permanent excellent recovery, and the birth history was quickly forgotten, if indeed anything abnormal at the time of birth had been observed. However, in those cases in which the amount of intracranial hemorrhage was not of sufficient degree to cause death and yet of larger quantity than could be entirely absorbed by the natural means of absorption (through the walls of the supracortical veins chiefly (80 per cent), sinuses, pachionian bodies, etc.), the babies only apparently recovered from the acute condition within a period of from two to four weeks and were even considered normal until the seventh month and usually within the first year when it was noticed that the child was not developing physically at the normal rate as to holding up its head and sitting up and later was retarded in beginning to walk and to talk. Usually within the latter part of the first year an increasing spasticity of either one or both legs appeared as part of a hemiplegic or a diplegic condition. It is in the latter chronic conditions of intracranial hemorrhage in the newborn that the etiologic factor of hemorrhage has been frequently overlooked owing to the paucity and even lack of the clinical signs at the time of the acute condition at birth—the cells of the cerebral cortex being only partially developed at the time of birth and thus even large cerebral lesions not being disclosed clinically. Then the later development of a chronic physical and mental impairment in a child apparently normal up to the latter part of the first year has been a most puzzling one, the factors of heredity, alcoholism, lues, etc., being most frequently considered. These observations regarding the character of the cerebrospinal fluid were made in the hope that the acute

condition of intracranial hemorrhage in the newborn will be more frequently recognized, so that its appropriate treatment—possible repeated lumbar punctures of spinal drainage together with the methods of increasing the blood coagulability—may be instituted early, while the blood is in fluid form and not after a period of days, when the hemorrhage that may not be absorbed has coagulated. Thus the hope that the permanent presence of a supra-cortical organization-residue—the future obstruction to free absorption of the cerebrospinal fluid and the underlying cause of varying degrees of increased intracranial pressure of cerebral edema in these chronic cases of cerebral spastic paralysis, can be prevented.

A brief summary of the series of 500 consecutive newborn babies on whom a lumbar puncture was performed within from twelve to twenty-four hours after birth, by my associates, Doctors A. S. MacLair<sup>29</sup> and G. E. Espejo<sup>30</sup> and through the courtesy of Doctors Child, Dorman and Ward at the City Hospital, Welfare Island, is as follows. In forty-five babies there was disclosed bloody and blood-tinged cerebrospinal fluid, that is, in 9 per cent of the entire series. One other baby dying before a lumbar puncture was performed—the puncture being made fifteen minutes after death—revealed at necropsy an extensive intracranial hemorrhage with bloody spinal fluid, this case however has not been included as having bloody cerebrospinal fluid. In as many as fifty babies, that is, 10 per cent of the entire series, no lumbar puncture was performed—in thirty-six a dry tap was recorded, and in fourteen the test was not performed, as seven babies were in severe shock and seven premature babies were in poor condition.

In making the test of lumbar puncture in this series, if bloody, blood-tinged or yellow and straw-colored cerebrospinal fluid was disclosed, then another immediate confirmatory puncture was made one interspace higher—merely to prove or disprove the presence of blood in the first test. In the bloody cases, another test was made within a period of twenty-four hours, and cerebrospinal fluid was drained of an amount not to lower the pressure below the normal 4 to 6 mm of mercury, these daily tests were repeated until the fluid became clear and under normal pressure. As many as seven punctures of drainage were necessary in several cases, and yet the average number was slightly over three.

There were three deaths in this series of newborn babies on whom a lumbar puncture revealed blood in the cerebrospinal fluid—two in the first hundred and one in the fourth hundred. Post-mortem examinations disclosed a large ventricular hemorrhage in the first, extensive supracortical hemorrhage and cerebral edema in the second, and large supracortical, basal, subtentorial and spinal hemorrhage in the third baby. Their com-

mon signs were stupor and refusal to nurse, convulsive twitches were present in only the third baby

The clinical signs suggestive of an intracranial lesion were most meagre and usually apparently lacking. Only seventy-three babies exhibited clinical signs, and their order of frequency was the following: muscular twitches of the feet and toes in eleven, of whom only four had bloody fluid, prolonged cyanosis in nine, and only in two was blood disclosed in the fluid, poor nursing in seven, of whom two had blood in the fluid, four were unusually drowsy and two of these had blood in the fluid, the presence of rigidity in two cases was very significant, in that both babies had bloody fluid, respiratory difficulties in mild degree, such as slightly irregular and labored breathing in fourteen babies, of whom only two had bloody fluid, and other signs, such as frothing at the mouth in one baby having yellow fluid, a supranuclear facial palsy in one having bloody fluid, and epistaxis in two of whom one had bloody fluid. That is, in seventy-three cases having clinical signs suggestive of a possible intracranial lesion, only twenty-five had blood in the cerebrospinal fluid and eight were not recorded. The spinal pressure as registered by the mercurial manometer in these seventy-three cases having clinical signs was increased in thirty, normal in twenty-eight and diminished in six. The anterior fontanel was flush in twenty-four, bulging in fifteen and depressed in twenty-five. The blood clotting time was normal in thirty-five, prolonged in six and decreased in ten. The mother's blood Wassermann test was positive in six. From the foregoing observations, the possible signs of an acute intracranial hemorrhage of mild degree at the time of birth are inconstant and apparently in many cases entirely lacking.

In the forty-five babies having blood of varying degree in the cerebrospinal fluid, thirty-three were males and twenty-two were first children, only four were premature babies. The labor was normal left occipito-anterior and right occipito-anterior in twenty-four, prolonged in seven, precipitate in three, low forceps in three, one of which followed a prolonged labor, medium forceps in four, breech extraction in two, version with breech extraction in one and a face presentation in one. The anterior fontanel was flush in twenty, tense and bulging in eleven, and depressed in fourteen. The cerebrospinal fluid was bloody in twenty-two, blood tinged in nine, and yellow in fourteen. The blood clotting time was within normal limits for each one of the babies having blood in the cerebrospinal fluid, varying from three minutes in one to ten minutes in another baby—the average being five and one-half minutes. The intradural pressure averaged 10 plus mm—the lowest being one at 2mm, one at 3mm and seven at 4mm, and the highest being

one at 26mm, one at 18mm, two at 16mm, one at 15mm and three at 14mm.

Seventeen babies became jaundiced, in only two of whom was the cerebrospinal fluid bloody and under 8mm and 14mm of pressure, respectively, the blood clotting time was four and one-half minutes in one, and five and one-half minutes in the other, five and three lumbar punctures of spinal drainage were necessary to obtain clear cerebrospinal fluid.

The Wassermann test was positive in both mother and child (4 plus) in only one case in which there was free blood in the cerebrospinal fluid, it was 4 plus in two mothers but negative in their babies, and 1 plus in two mothers but negative in their babies, and one plus in one baby but negative in the mother.

As noted above, the blood clotting time has been within normal limits for each baby having free blood in the cerebrospinal fluid, and it has been prolonged in only six cases, and yet these six babies had clear cerebrospinal fluid. The fact that in this series of cases the blood clotting time was taken within forty-eight hours after birth—and it has been observed that even in the condition of hemorrhagic disease in the newborn the blood clotting time may be within normal limits until the third day after birth, when it becomes lengthened—may account for the low incidence of a prolonged clotting time in this series. Besides, the bleeding time may be lengthened and yet the clotting time be within normal limits—the former condition being the more important and serious factor in the case of intracranial hemorrhage.

#### IMPRESSIONS

1 Intracranial hemorrhage of varying degree in the newborn occurs rather frequently, in 9 per cent of this series.

2 Its acute signs are often meagre and may be apparently entirely absent, the more common signs being from drowsiness to stupor, from difficulty to refusal to nurse and from muscular twitches to general convulsive seizures.

3 First born, full term males having difficult prolonged labors are more liable to this complication, forceps being used as a last resort rather than their early application, medium forceps and breech extractions.

4 Hemorrhagic disease of the newborn is not a common etiologic factor at least in this series of cases, in which puncture was done and tests were made within from twenty-four to forty-eight hours after birth.

5 Lumbar puncture as an early diagnostic method when the hemorrhage is still in fluid form, and as a therapeutic means of spinal and cranial drainage, is a simple and safe procedure in the absence of severe shock.

6 The early recognition and appropriate treatment of the acute condition of intracranial hemorrhage in the newborn may thus lessen that large

chronic group of physically impaired and mentally retarded children

## COLLE'S FRACTURE\*

By F F McGAULEY, MD, F.A.C.S., SCHENECTADY, N Y

TODAY it is amusing to review the literature on Colle's Fracture and to note how different surgeons apologize for dealing with such a commonplace and simple subject. Yet 75-80% of Colle's fractures should carry an apology for the results obtained, according to the opinion of the late John B Murphy. At the present time, I believe the results are much better than Murphy found, but they are still far from the ideal.

The *Edinburgh Medical and Surgical Journal*, 1814, Volume 1, page 182, contains an article "On the Fracture of the Carpal Extremity of the Radius," by A Colles, M.D. This is a purely objective description and treatment of the condition, and contains 1,528 words. This article is a masterpiece and is worth reading to note how much can be seen without the X-ray.

As a result of automobile accidents many unusual fractures of the radius contiguous to the wrist should change the title of such fractures to a Colles-Ford, Auto-Colles, or some similar epithet if we do not call them lower radius fractures. Some surgeons make a special classification such as simple Colles, Colles resulting from auto cranking, Colles fractures extending into joint, impacted Colles, etc. However, we have made no such classi-

fications, but recognize one injury, that is, a broken radius, and treat it one way with an occasional modification. It would seem that most surgeons make a hard task of an easy one and get into trouble, which is characteristic of the teachings in some medical schools. As a rule most young doctors know several names and classifications of broken wrists, but are unable to set one properly because they cannot classify the injury with the proper method of reduction.

Undoubtedly a high morbidity results from the average treatment allotted to broken wrists by the general practitioner. There is no reason why he should not reduce a fractured radius as well as the best trained surgeon. In many cases the practitioner is surrounded by surgeons and a first-class hospital, consequently he turns over his fractured wrists to surgeons. But he should not be obliged to turn away his Colle's any more than he should call in obstetricians to take care of his obstetrical practice.

I am bringing this subject to your attention because I believe we have something interesting from a diagnostic, treatment and disability standpoint.

In reviewing the work for the past five years in the offices of Drs McMullen, Lenz and myself, we have treated 264 broken radii either at the office or the Ellis Hospital. Most

\* Read before the Fourth District Branch of the Medical Society of the State of New York at Plattsburg, October 9 1926

of the cases were treated at the office, as it is an office procedure

From a diagnostic standpoint it is occasionally impossible without the aid of an X-ray to make a positive diagnosis, but in most cases one can carefully examine the wrist and may make a fairly accurate diagnosis. First, there is a history of an injury, either from cranking an auto or one has had a fall with the outstretched hand bearing the weight of the body. The injury may have happened several days previously, but the disability is usually becoming more marked because the fracture was not reduced. Secondly, there is usually some swelling of the hand above the styloid processes of the radius and ulna, with obliteration of ulna prominence. There may or may not be any marked deformity due to a posterior dislocation of the lower fragment. Thirdly, one of the most important signs is tenderness which is usually more marked directly over the fracture. The patient is usually able to move the fingers, contrary to the lay opinion. Fourth, and undoubtedly the most important that is made in the examination, is the differences in the level of the styloid processes of the radius and ulna. When one places the index finger of each hand just at the tips of the styloid processes of the radius and ulna, if there is a fracture one will note the radius is on a level with the ulna or perhaps the radius is a little higher (proximal to the elbow) than the ulna, which is just the reverse of a normal wrist. If there is an impaction without dislocation this will be very marked and such cases are the ones which are usually overlooked.

As to the X-ray in making a diagnosis, there is often no difficulty in making a diagnosis without it. The X-ray is mainly used to determine just how much manipulation is necessary to reduce the fracture.

As to the time of reduction, we feel that early reduction of a fractured wrist from a morbidity standpoint is as important as the early treatment of a strangulated hernia from a mortality standpoint. Early reduction means early recovery—delayed reduction means a prolonged and inexcusable disability. As shown in our case records, the short disability in a great many cases, we believe, was due to immediate reduction.

As to the treatment—the first stage of ether anaesthesia or nitrous oxid gas is used. As soon as the patient is anaesthetized, the surgeon places his foot on a chair to use his knee as a support. The broken wrist is taken over the surgeon's knee, both thumbs are placed over the back of the radius above and below the line of fracture. Pressure is then exerted by the thumbs in order to break up the fracture and to unlock the fragments. The lower fragment is then brought forward in flexion and the hand

is hyperflexed toward the ulna side. The styloids are then checked up to make sure that the styloid of the radius is distal (near the hand) to the styloid of the ulna. The surgeon's fingers are run up and down the dorsum of the hand and wrist to make sure the lower fragment has been pushed forward.

In carrying out this maneuver one should be careful not to pull or twist the wrist any more than is absolutely necessary. This is the usual procedure with most fractures of the radius.

However, if the X-ray shows that the radius has been fractured into the joint and the fragments are dislodged, the wrist is partly circumducted with the ulna as a fixed point, that is, given a half turn in both directions in order to allow the fragments to drop back in their respective positions. This is followed by hyperflexion toward the ulna side.

As to the splints, we use a dorsal molded plaster splint padded with sheet wadding or gauze, extending from metacarpophalangeal joint up to about two-thirds the distance of the forearm. After holding the plaster in place for a few minutes after it hardens, the bandage is applied (not too tightly). It is imperative that the plaster splint be much wider than the width of the arm at the widest point.

After reduction an X-ray is always taken to make sure the fragments have been properly reduced, and in case the reduction is not successful the patient is again anaesthetized and the maneuver repeated. We have done this four or five times in bad fractures and occasionally have had to use the fluoroscope in an obstinate case. (This, however, is very rare.)

An occasional reverse Colles (which happens about once in two hundred cases) should be put up in just the reverse position in a cock up splint, rather than hyperflexed.

As to the after care, the patient is seen within twenty-four hours and the cast is removed. The hand is lightly massaged to restore the circulation. After a few minutes the splint is replaced and another bandage applied. The next day the cast is removed and more massage is given. The cast is then cut down so as to cover only the back of the wrist (a distance of about four inches) and the patient is instructed to use his fingers as much as possible. The patient is seen daily and massage and electrical treatment is started immediately. The splint is usually taken off at the end of a week or ten days, but the patient wears a small bandage to remind him that his wrist has been broken.

Electrical treatment and massage is given daily and the patient is usually discharged at the end of three or four weeks.

As to the X-ray role in the diagnosis and treatments of fracture of the wrist, I feel sure it is of the greatest importance. If the roentgenologist is too charitable he will get one

into all kinds of difficulty. It is very imperative to have a proper interpretation of the X-ray, particularly as to whether the fracture is properly reduced. There are a few important X-ray points:

First. In the antero-posterior view, does the radius and ulna make an arc parallel with the proximal row of carpal bones?

Secondly. Is the radio-ulnar articulation satisfactory?

Thirdly. Is the styloid of the radius distal to the styloid of the ulna?

In the lateral view first note that the deformity has been reduced so that there is no displacement or rotation backward of the lower fragment—that the articular surface of the radius does not tilt backward, but faces anteriorly.

1. In reviewing the last fifty cases of uncomplicated Colles, the average time from date of fracture to discharge was twenty-eight days.

2. One conclusive observation we have made is that little manipulation at reduction usually shortens the convalescence. In the cases that have to be treated or reduced a second or third time there is lengthy disability.

3. Also the morbidity is less in cases where the accident happens out of duty, rather than the cases that occur in line of duty. For example, a musician who fractures his arm cranking a pleasure car has a shorter disability than the truckman who sustains a similar injury cranking his delivery truck. Women (particularly the old-maid type) have a prolonged disability, while the old family man forgets his aches and pains and returns to his work. Musicians, such as pianists or violinists, as a rule, have the shortest disability of any class.

4. We have never seen a recurrence of a fracture nor a rotation of lower fragment after the fragment had been properly reduced in spite of the short time that the splints are applied.

I will show a few slides to bring out some interesting points.

## EVALUATION OF THE ICTERUS INDEX TEST IN GASTRO-ENTEROLOGY\*

By EMANUEL W. LIPSCHUTZ, M.D., BROOKLYN, N. Y.

Associate in Gastro-Enterology, N. Y. Polyclinic Medical School and Hospital

AS far back as 1913, van den Bergh<sup>1</sup> and his coworkers have described a quantitative method for the determination of bilirubin in the blood serum, making use of the diazo reaction of Ehrlich as the basis of the test. The latter depending upon the development of an azo dye, when an acid solution of a diazonium salt is added to an alcoholic solution of bilirubin. They found that bilirubin in a dilution of 0.7 mg per liter gives a positive reaction to this test.

Meulengracht<sup>2</sup>, in 1920, described a colorimetric method for determining relative quantities of bilirubin in the blood serum, using a dilute solution of Potassium Bichromate as a standard. The latter being prepared in a dilution that matches the color of the average normal serum. Since then greater interest has been stimulated in the use and clinical application of the test, modifications of which have been evolved by Gram<sup>3</sup>, and later by Bernhard and Maue<sup>4</sup>, the quantity of bilirubin present being expressed in terms of units. The number of units a given quantity of blood contains, indicates the so-called "Icterus Index."

The technic employed in determining the icterus index is quite simple. One cubic centimeter of the patient's serum is diluted with nine cubic

centimeters of normal saline, and this is matched in a colorimeter, with a standard, which is a solution of Potassium Bichromate in a 1-10,000 dilution. The reading of the standard divided by the reading of the unknown, multiplied by 10, the dilution of the serum, gives the icterus index in terms of units. Certain rules must be observed in order to obtain good results. The blood must be collected in a dry vessel, with a dry needle, and kept in a cool place preferably in the ice box, for several hours, so as to hasten clotting and prevent hemolysis, since the test can not be performed on hemolyzed blood.

A. R. Bernheim<sup>5</sup>, in the early part of 1924, gave a very comprehensive description of the icterus index test, having performed the same on a series of 485 cases including various diseases. According to her findings the normal icterus index is between 4-6 units, above six units is considered abnormal, the individual being in a state of hyperbilirubinemia. Between 6-15 units it is presumed that the patient is in a state of latent icterus, as soon as the bilirubin reaches 15 units, clinical jaundice usually becomes apparent. Barrow et al<sup>6</sup>, in a subsequent communication, have fully corroborated Bernheim's findings as to what constitutes a normal icterus index, and the various diseases in which the latter is increased. Of the gastro-intestinal diseases, infec-

\*Paper read before the New York Polyclinic Medical Society, Feb. 1, 1926.

of the cases were treated at the office, as it is an office procedure

From a diagnostic standpoint it is occasionally impossible without the aid of an X-ray to make a positive diagnosis, but in most cases one can carefully examine the wrist and may make a fairly accurate diagnosis. First, there is a history of an injury, either from cranking an auto or one has had a fall with the outstretched hand bearing the weight of the body. The injury may have happened several days previously, but the disability is usually becoming more marked because the fracture was not reduced. Secondly, there is usually some swelling of the hand above the styloid processes of the radius and ulna, with obliteration of ulna prominence. There may or may not be any marked deformity due to a posterior dislocation of the lower fragment. Thirdly, one of the most important signs is tenderness which is usually more marked directly over the fracture. The patient is usually able to move the fingers, contrary to the lay opinion. Fourth, and undoubtedly the most important that is made in the examination, is the differences in the level of the styloid processes of the radius and ulna. When one places the index finger of each hand just at the tips of the styloid processes of the radius and ulna, if there is a fracture one will note the radius is on a level with the ulna or perhaps the radius is a little higher (proximal to the elbow) than the ulna, which is just the reverse of a normal wrist. If there is an impaction without dislocation this will be very marked and such cases are the ones which are usually overlooked.

As to the X-ray in making a diagnosis, there is often no difficulty in making a diagnosis without it. The X-ray is mainly used to determine just how much manipulation is necessary to reduce the fracture.

As to the time of reduction, we feel that early reduction of a fractured wrist from a morbidity standpoint is as important as the early treatment of a strangulated hernia from a mortality standpoint. Early reduction means early recovery—delayed reduction means a prolonged and inexcusable disability. As shown in our case records, the short disability in a great many cases, we believe, was due to immediate reduction.

As to the treatment—the first stage of ether anaesthesia or nitrous oxid gas is used. As soon as the patient is anaesthetized, the surgeon places his foot on a chair to use his knee as a support. The broken wrist is taken over the surgeon's knee, both thumbs are placed over the back of the radius above and below the line of fracture. Pressure is then exerted by the thumbs in order to break up the fracture and to unlock the fragments. The lower fragment is then brought forward in flexion and the hand

is hyperflexed toward the ulna side. The styloids are then checked up to make sure that the styloid of the radius is distal (near the hand) to the styloid of the ulna. The surgeon's fingers are run up and down the dorsum of the hand and wrist to make sure the lower fragment has been pushed forward.

In carrying out this maneuver one should be careful not to pull or twist the wrist any more than is absolutely necessary. This is the usual procedure with most fractures of the radius.

However, if the X-ray shows that the radius has been fractured into the joint and the fragments are dislodged, the wrist is partly circumducted with the ulna as a fixed point, that is, given a half turn in both directions in order to allow the fragments to drop back in their respective positions. This is followed by hyperflexion toward the ulna side.

As to the splints, we use a dorsal molded plaster splint padded with sheet wadding or gauze, extending from metacarpophalangeal joint up to about two-thirds the distance of the forearm. After holding the plaster in place for a few minutes after it hardens, the bandage is applied (not too tightly). It is imperative that the plaster splint be much wider than the width of the arm at the widest point.

After reduction an X-ray is always taken to make sure the fragments have been properly reduced, and in case the reduction is not successful the patient is again anaesthetized and the maneuver repeated. We have done this four or five times in bad fractures and occasionally have had to use the fluoroscope in an obstinate case. (This, however, is very rare.)

An occasional reverse Colles (which happens about once in two hundred cases) should be put up in just the reverse position in a cock up splint, rather than hyperflexed.

As to the after care, the patient is seen within twenty-four hours and the cast is removed. The hand is lightly massaged to restore the circulation. After a few minutes the splint is replaced and another bandage applied. The next day the cast is removed and more massage is given. The cast is then cut down so as to cover only the back of the wrist (a distance of about four inches) and the patient is instructed to use his fingers as much as possible. The patient is seen daily and massage and electrical treatment is started immediately. The splint is usually taken off at the end of a week or ten days, but the patient wears a small bandage to remind him that his wrist has been broken.

Electrical treatment and massage is given daily and the patient is usually discharged at the end of three or four weeks.

As to the X-ray role in the diagnosis and treatments of fracture of the wrist, I feel sure it is of the greatest importance. If the roentgenologist is too charitable he will get one

## THE ANNUAL MEETING

Preparations for the Annual Meeting of the Medical Society of the State of New York, in Niagara Falls, are approaching completion. The Scientific Committee has nearly completed the program of the scientific sessions. Mr. Tufts, the Advertising Manager, has sold nearly all the available booths for commercial exhibitors. The local Committee on Arrange-

ments has made provision for the courteous entertainment of the physicians and their wives. Altogether the meeting promises to be full of interest and value.

Remember the dates—the four days, Monday to Thursday, Many ninth, tenth, eleventh, and twelfth. Come and make the attendance a record one.

tion of the biliary tract, such as chronic cholecystitis, cholangitis, infective type of cholelithiasis, and hepatitis, whether secondary to gall-bladder and duct infection or primary, the result of various causes, head the list. Duodenal ulcer cases have also given high icterus index readings, probably resulting from direct liver infection, from the ulcerated area in the duodenum, or a cholangitis resulting from an associated duodenitis.

One frequently encountered entity in gastro-enterology, namely intestinal toxemia, displays almost invariably a high icterus index, a condition which has hitherto not been mentioned in any of the recent work done on the icterus index. It is this important fact that I want to emphasize in connection with intestinal toxemia, from observations which I have made on 64 cases. These patients, suffering from a toxemia show a marked retention of bilirubin in the blood stream, which may be due to the fact that the hepatic cells are overburdened in their attempt to detoxify the system, and are unable to filter the bilirubin in normal quantities, or perhaps toxic products from the colon, reaching the liver cells by means of the portal circulation, render them less permeable to the excretion of bilirubin. The same mechanism in all probabilities is responsible for an increased icterus index in cases of biliary tract infection.

A Bassler<sup>7</sup>, several years ago, has called attention to cases of intestinal toxemia of the saccharobutyric type, in which cirrhotic changes in the liver could definitely be demonstrated clinically. He attributed these liver changes to the action of various volatile acids which are produced in the colon, and are carried to the liver by the portal stream, exerting their deleterious effect upon the hepatic cells. The high icterus index values obtained in those cases seem to prove the correctness of his contention.

In cases of so called "gastric neurosis," the icterus index is always within normal range. This fact is of great importance, serving as a differential point between cases presenting symptoms purely neurotic or reflex in nature and those manifesting symptoms resulting from actual infection somewhere in the gastro-intestinal tract, such as the biliary tract or colon, the latter cases being very frequently encountered in gastro-enterology. Since we have advocated the icterus index test in our clinic, it seems that fewer cases are diagnosed as gastric neurosis. In my series of cases, including both clinic and private patients, I find that the icterus index is as a rule higher in cases of intestinal toxemia than in unobstructed cases of biliary tract infection. This is quite an important differential point where the diagnosis between the two conditions is more or less obscure. This hyperbilirubinemia is at times

so strikingly marked in cases of intestinal toxemia, as to impart a dark amber color to the serum, making it readily discernible that one is dealing with a serum that will give a high icterus index reading. On examining those sera I almost invariably find that the icterus index ranges between 10-14 units, rarely falling below 10 units, whereas cases with unobstructed biliary tract infection display an index generally below 10 units. If a high icterus index (above 10) is encountered in a case where gall-bladder symptoms predominate and one is led to diagnose the condition as some biliary infection, such as cholecystitis, a more thorough search will reveal that one is dealing with two coexisting conditions, namely, a biliary tract infection with a super-imposed intestinal toxemia, thus accounting for the degree of hyperbilirubinemia present.

Various authors have ascribed great prognostic value to the icterus index test. Cases exhibiting a high index resulting from biliary tract infection, have shown a normal index following cholecystectomy. Those reported cases have evidently been suffering from a frank cholecystitis or cholelithiasis, without a complicating intestinal toxemia, which is so usual in those cases. I have two cases in my series that have been cholecystectomized, one about seven years ago, the other six months ago, still they both show a persistence in their high index. These two patients are suffering from a toxemia with probably a certain degree of hepatitis.

We are at present conducting a series of experiments to determine the effect of various forms of therapy on the icterus index in cases where the latter is increased. The favorable outcome of those experiments promises to give us a better idea of the prognostic value of the icterus index test in gastro-enterology. The above described test with its differential value, is not offered as a substitute for the diagnostic procedures generally employed, it was only meant to emphasize its importance as a diagnostic aid in the recognition of the diseases of the alimentary tract.

star to last for ages,"—and to prove it he says that two hundred years ago, during a conjunction of Mars and Saturn the pneumonic plague "Raged among all the people of the east which, expelling the bloody sputum from the palpitating chest, frequently ended life on the fourth day" His facts were sound, and his fancies were the science of his day, but he adds with a modern spirit, "However, I am well aware that it is difficult to say what Heaven does effect and in what fashion, and to find a certain assured cause for every event Sometimes the result is delayed for such long periods and at the other times fortune and various accidents intervene and thus mislead us"

Then follows remarks on the kinds of contagion, some of which affect trees only, some the crops, some, animals, and some, men only "And now," he says, "I will teach thee the course and symptoms of this detestable malady, and would that Apollo might grant that this, my chronicle shall live for ages Perchance, indeed, some day our posterity may be glad to learn what the signs and appearance of this pestilence were For after years have rolled away, when it shall once more lie buried in the blackness of night, then again, after long ages, it will rise anew, and once more a coming age will gaze with wonder at it"

Then the disease is described in a way which would do credit to a Holmes or an Osler "When the disorder had been caught no very manifest signs of it appeared until the moon had four times run his monthly round In the interval the patients, oppressed with unwonted torpor, dragged but lazily their work, and the bodily functions were executed with difficulty" Then are described the primary lesion and the pains through the body, and the eruption, "the pustule which are much like the top of an acorn", and finally the ulcers

The book ends with an imprecation of the gods for adding to the pestilence the horrors of war and slaughter in upper Italy

Book two is on treatment, and begins with excellent directions regarding rest and exercise, diet, and drinking Bleeding is advised, and herbs, and especially the orange If these common remedies fail, then "Hasten to subject thyself to strong treatment and overcome the sore malady in the briefest space of time" He then describes a fumigation of the whole body with a mixture of styrax, cinnabar, red oxide of lead, and antimony But this, he says, is too strong and may suffocate the patient He says that there is a wonderful virtue in quick-silver, and then he gives a four-page legend of how its virtues were revealed by the underground gods to a patient named Ilceus "The fame of this new miracle soon got abroad, and the never failing remedy found acceptance among all ranks The first trials were made with the fluid silver and hog's lard" Fracastorius pre-

fers it mixed with olive oil, sulphur, and assafoetida, and says, "Do not think it filthy or low to smear and rub the whole of the body with these, by such means the disease is removed from the body and nothing can be filthier than it is Be firm of purpose Health will point out to thee certain signs Thou shalt behold the liquefied dregs of the malady pour, with the foul saliva, in a constant torrent from the mouth, and shalt wonder at the huge stream of disease at thy feet But now victorious, let it be thy constant care to wash thy body and anoint thy joints with fragrant ointment"

The third book has little medical or scientific interest to modern readers, although it is excellent literature "It concerns the Guaiac tree, the sacred wood which alone moderates and stills the pains and puts an end to suffering" It tells a fanciful story of Columbus, guided by Nercids safely to shore, where his more youthful followers saw some sacred birds and "Snatched up their fearful hollow-tubed arquebuses laden with heavy balls, and pregnant with destruction Forthwith they charged these with willow charcoal, sulphur, and nitre, and fired the powder with the matchwood kept always burning All the locked-up fiery force suddenly blazed forth, and the wadding having burst, the balls flew ringing through the air and stretched the birds lifeless on the ground"

One bird, escaping, uttered a threat of pestilence to fall upon the party

Then is told the meeting of Columbus with the king of the land, and the rites performed by the people with the Guaiac tree, and its application to the treatment of a number of natives who were afflicted with the disease to which the Spaniards were doomed by the sacred bird The last three pages of the book tell the origin of the rites, how Syphilus, a herdsman, cursed the sun god for a draught and instituted the worship of his kind, and so brought down the pestilence on himself and his people. As Syphilus was about to be sacrificed, the Sun God accepted a heifer in his stead, and sent the Guaiac tree to heal the people

Almost the only bit of science in the third book is an excellent description of the Guaiac tree and the method of making a decoction from its bark Syphilus is simply a literary character introduced almost at the close of the poem, Fracastorius named the poem "Syphilis, or the French Disease" in the same way that a modern author might name a history of the revolution "Washington, or the War of Independence"

Fracastorius was the Oliver Wendell Holmes and the Weir Mitchell of four centuries ago, and his scientific poem has a thrilling interest for the modern reader

## THE POEM "SYPHILIS"

The literature of medicine is fascinating to one who delves into the origin of the names of diseases and of current conceptions of their nature. It has often been stated, for example, that the word syphilis comes from the name of a character in an early Italian poem, but how many physicians have read the poem, or know anything about its plot?

The poem is an excellent piece of literature and full of interest to the medical reader. It is entitled "Syphilis, or the French Disease." It was published in 1530 soon after the disease had become a widespread epidemic. It was written in Latin hexameters after the pattern of Virgil's *Aeneid*. It covers about thirty-five printed pages, and consists of three books. Book one is a description of the disease, book two describes the remedies, especially mercury, and the legends of its discovery, and book three describes guaiac and the legend of the revelation of its virtues in the application of the treatment of a shepherd named Syphilus. The Library of the New York Academy of Medicine contains several copies of Latin text and its translation, of which probably the most readable is one in which the Latin and English are printed on facing pages. This particular copy was published by the Sloane Society, London in 1884, and was presented to the Academy by Dr. R. W. Taylor, whom the older physicians will remember as the Professor of Genito-Urinary diseases in the College of Physicians and Surgeons, New York City.

The author states the object of the poem in its opening lines, after the plan of the *Iliad* and *Aeneid*, as follows:

"What various causes brought to us, from what seeds sprang that strange disease, for long drawn ages seen by no human being, which in our time raged through all Europe, part of Asia and the cities of Africa, which forced its way into Latium by means of the disastrous wars carried on by the French, and, indeed took its name from that people, also what cure exists for it, and what help the use of this, and great skill of men in the difficult straits of life furnished us with, the aid lent by the gods and the gifts bestowed by heaven, these I will essay to sing."

What qualifications had the author of the poem to carry out the plan? Jerome (Hieronymus in Latin) Fracastorius was born in 1483 in Padua, Italy, and spent his seventy years of life in the vicinity of that city. He was deemed to be the most learned man of his time and included the practice of medicine among his accomplishments, although his principal occupation was that of a literary scholar. He published the poem "Syphilis" when he was forty-seven years of age. Sixteen years later he published a book on "Contagions," which

entitles him to honor, for he was the first writer to put forth the modern idea of contagion by the transfer of infective material, as from "one grape or pear to another." He made the three-fold classification of transfer, (1) by contact, (2) by fomites (a term which he seems to have originated), and (3) by means of pestilential air. He seems to have considered that syphilis belonged to the third class of contagious diseases.

The poem "Syphilis," is a combination of scientific description and poetical fancy, but its remarkable characteristic is that the reader may easily recognize what is fact and what is fancy in the mind of the author. Moreover, the scientific parts are written in a clear and interesting style like that of the best medical writers of England and America.

After the introduction to the poem, Fracastorius calls on the goddess Urania to disclose the land of origin of the disease,—"Whether, borne over the western seas, it reached our hemisphere by that port on the Iberian shore, from which a chosen band issued to dare the waves and the heaving plains of an unknown ocean, and seek out lands seated in another world, for there they say every city suffers perpetually from the ravages of this disease, and that, fostered by a morbid quality of the air, it is always wandering about, and spares but few."

The author answers the question by pointing out epidemiological facts which would do credit to a modern investigator. He cites the widespread prevalence of the disease and the fact that in Spain, which first came in contact with the New World, the disease was no more prevalent than elsewhere in Europe. Yet, for poetic reasons, he says:

"But in the great ocean beneath the setting sun, where a miserable race inhabit the newly found world, it is perpetually springing up, and is familiarly known in every part. There the air and a suitable soil generate it. The air is the father of things. Prone from its yielding nature to become impure in many ways, the self-same element afflicts mortals with serious diseases. And now learn the way it imbibed that contagion, and what changes revolving years can effect."

Then follows four or five pages of description of the effects of Phebus, the sun, on the earth as he travels north and south. Fracaster argues that perhaps the sun may traverse a fresh path, new animals may spring up and giants arise who will expel the gods from Olympus. "These things only weighed, there is no need to marvel if in the course of time the wide air grows rank with new diseases, and if contagions, unknown among the sufferers of our day, arise under some particular

# MEDICAL PROGRESS

**Gentian Violet and Acriviolet in the Treatment of Pernicious Anemia**—H. Milton Conner reports his experience with 23 cases of pernicious anemia in which the administration of gentian violet was begun between 7 and 12 months prior to the time of writing. In most instances in which the dye was used for a sufficient time there was a gratifying rise in the percentage of hemoglobin and in the number of erythrocytes to approximately twice their average values before treatment. There was also an increase in leucocytes, in some cases very marked, in others less striking. In several cases the treatment had to be discontinued because of untoward reactions to the dye, evidenced by nausea and vomiting, and sometimes by an increase in diarrhea. Gentian violet may be given in solution, capsules, or enteric coated tablets. The solution, although sometimes difficult to take, has seemed to be the most effective. Patients are usually started on from 5 to 15 c.c. of a 1 to 1000 aqueous solution of the dye after each meal, the dose being increased one or more cubic centimeters a day, until 50 c.c. or more are taken three times daily. It has also been given in doses of one or two half-grain enteric coated tablets after each meal. Acriviolet has been given in doses varying from 0.1 to 0.4 grain in enteric coated tablets, although sometimes much larger doses are tolerated. Probably the best results will be obtained when the dose is gradually increased to the limit of tolerance (as indicated by nausea and vomiting). In most cases dilute hydrochloric acid was also given, and in 11 cases transfusion was carried out as well, though the most striking results were obtained in the cases in which no transfusions were given. There is a strong possibility that local application of the stronger solutions of the dyes might be beneficial in the treatment of the glossitis of pernicious anemia. While the series of cases is too small and the time since the inception of the treatment is too short for conclusions to be drawn, the author believes that the occurrence of such marked remissions as he records, and the absence of recurrences in so many cases, may be more than a coincidence. He urges that others test the effect of the dyes in pernicious anemia.—*Medical Journal and Record*, January 5, 1927, cxxv, 1

**Treatment of the Preeclamptic Stage with Ultraviolet Light**.—Anton Mayer notes the fact that eclampsia is less apt to occur in the summer months when the sun is high and states that the old time practitioner used to have gravidæ with preeclamptic symptoms take sun baths with the aim of lowering the blood pressure and detoxicating the maternal organism. In

1922 Hochenbichler was the first to use artificial solar light for this purpose and reported that he was able thereby to cause a fall in the blood pressure. The present author took up the subject and has now tested the remedy in 25 cases of preeclampsia. Like his predecessor he was able to bring down the blood pressure notably—from 20 to 40 mm of mercury. The patients were all primiparæ and all presented the usual evidences of preeclampsia, including high blood pressure, albuminuria, casts, edema of the feet, headache, etc., etc. Of the 25 women all but one took the full treatment and of the 24 not one developed eclampsia, the exceptional patient escaped the treatment and developed convulsions, although they did not end fatally. The expected incidence in this service should have been at least five cases, the annual incidence having been from two to eight.—*Wiener klinische Wochenschrift*, December 23, 1926

**The Halle Operation for Ozena**.—R. A. Barlow states that the Halle operation is the most successful measure thus far suggested for the relief of ozena and atrophic rhinitis—conditions in which medicinal applications afford only transient improvement and surgery has been obviously unsuccessful. The Halle operation can be performed under local anesthesia as ordinarily induced for nasal operations. When the patient is prepared all crusts are removed and the mucosa cleansed with dilute oil of lavender. The incision is started in front of the attachment of the middle turbinate, on the lateral wall of the nose, is carried down anterior to the attachment of the middle turbinate, and across the floor of the nose to the septum. The incision is then carried through the periosteum to the bone. The periosteum of the floor of the nose is elevated to the junction of the soft and hard palates, and from the septum to the rise of the lateral wall. An opening is chiseled into the antrum, through the vertical incision in the lateral wall. With the chisel flat and pointed in the lower end of the vertical cut, the instrument is driven gently backward under the elevated periosteum in such a way that the antral wall is cut parallel with the floor. With the chisel inserted in the vertical cut, the lateral nasal wall is forcibly pried out until it hangs vertical in the nasal chamber. The turbinates and the corresponding areas on the septum, which have been previously scarified, are in apposition to the septum. The antrum is wiped out and packed with iodoform gauze to maintain the lateral nasal wall in contact with the nasal septum until adhesions form between these structures. The packing is removed at

## PUBLIC HEALTH, PROTECTIVE AND PREVENTIVE

The Governor's hearing on County Health Departments, described on page 314 of this Journal, brings the establishment of such departments acutely to the attention of physicians and county medical societies. Physicians generally recognize that the adoption and practice of public health measures are responsibilities which rest upon the community as well as upon the individual citizens. This argument is set forth in an editorial in the January 15 issue of this Journal entitled "County Health Officers." The present system of a rural health department in each town and village reaches the individual citizen in the face of actual danger. The proposed plan of a county health department would deal with community conditions whether or not an immediate danger is threatened. Local health work is therefore *protective*, while that of the proposed county department is *preventive*.

The county health department will do protective work as well as the preventive form. It

will be ready to assist the local villages and towns in the face of emergencies, such as the outbreak of an epidemic, but its distinctive work will be to anticipate trouble and educate the people in prevention before disease is at the door of the community.

There is need of individual health protection and of concerted preventive work, and, too, there is need of both local health officers and of county departments of health. The law permitting the establishment of county units continues the present system of local health officers. The Cattaraugus County Health Department, which is accepted as the standard form of county health unit, still retains the health boards and health officers of its villages and towns, and these local health officers are doing their work in a broader and more efficient way than ever. One must take their work in consideration when estimating the accomplishments of the Cattaraugus County Health Department.

## APOLOGIES TO BRONX COUNTY

Two hundred wrappers of the February first issue of this Journal, intended for members in Bronx County, mysteriously disappeared from the printing office, and their loss was not discovered until the Bronx County physicians began to inquire where their Journals were. The officers of the Medical Society have no way of determining who has failed to receive their

Journals. If any member will notify the office of the Editor or the Secretary of the Society, the missing Journal will be mailed to him at once.

The editors apologize to the Bronx County for omitting the name of its president, Dr. L. A. Friedman, from his inaugural address printed on page 261 of the March 1 issue of this Journal.

## LOOKING BACKWARD

## This Journal Twenty Years Ago

The typhoid epidemic in Scranton—The following editorial from this Journal for March, 1907, illustrates the difficulties under which public health authorities had to contend in the days when public sentiment regarding sanitary standards was in process of formation.

"The State Board of Health in Pennsylvania showed its efficiency by taking hold of the typhoid problem in Scranton before the local authorities had awakened to action in the recent epidemic. The water supply of the city was suspected from the first, but as this was owned by a corporation of influential and much respected citizens, as has been the case in other afflicted towns, there was much local delicacy about indulging in any incriminations. In compliance with the suggestion of some unusually bold spirit, the water company did shut off one reservoir which was notoriously polluted. This did not stop the epidemic because, as was discovered later, there was a frequent flow from one reservoir into the other.

"When the fever had been epidemic for

nearly a month, the State Board of Health came upon the scene and discovered the typhoid bacillus in the city water. People were instructed to boil the water and, the source of the infection being positively known, the epidemic began to abate. In the meantime, during the month of December, there were nearly a thousand cases of typhoid, and seventy-five deaths. The money loss in that single month alone would have been sufficient to have constructed an entirely new water system.

"The interesting feature is that there were men in Scranton who knew the danger and warned against it. The negligence of the municipalities in connection with this disease has become notorious. Some day a court will be convinced of the negligence, and then the door will be open for the recovery of damages, and perhaps the municipalities will prize more highly the monetary cost of the negligence than they do the health of their citizens, and we shall witness a general cleaning up of water supplies."

these may undergo mutations with a corresponding confusion in regard to the toxins produced. To throw more light on the subject Deicher carried out a course of experiments with different forms of streptococci and reached the conclusion that the organisms which transmit the disease are found only in the throats of the patients and in the pus of the purulent complications, the skin and urine, he thinks, do not participate at all. The scarlet fever germ may be found also in abundance in the immediate vicinity of the patients. After isolation of scarlet fever patients for a period of six weeks, examination has shown that the organisms are still present in the tonsils in 100 per cent of the cases. The assertion is made that the hemolytic streptococcus can be transformed into a nonvirulent green streptococcus, and thus again back to the original pathogenic form—*Deutsche medizinische Wochenschrift*, December 17, 1926.

**Relationship Between Chronic Tonsillitis and Chronic Nephritis**—Dr. Wichert, a rhinolaryngologist, writing in the *Muenchener medizinische Wochenschrift* of November 12, 1926, emphasizes the increasing evidence of the connection of chronic tonsillitis with chronic nephritis and likewise with chronic polyarthritis, appendicitis, endocarditis, etc. It is of course by no means easy to establish this relationship. It is only exceptionally that we find redness of the tonsils and can express pus from the crypts. The existence of an old tonsillitis may be shown in various ways—by the enlarged and cleft condition, the adhesions between the capsule and parenchyma, etc. It may be enough to note that the tonsil is organically inferior and should be extirpated, especially if the patient already shows signs of nephritis. At the Tübingen University there has of late been good teamwork between the rhinolaryngologist and internist so that the author has been able to assemble a series of 27 cases of the combined disease. All the patients suffered from chronic nephritis which did not respond to ordinary treatment, and in all of them the tonsils were ablated and the results then followed up. Work on the series began five or more years ago. In all but three patients contact has been maintained, these three having succumbed to uremia. In eight others the nephritis was uninfluenced, although three of these are still able to work. On the other side of the ledger nine seem to be permanently cured, the urine being normal, while four more are well and fully active although still presenting albumin in the urine.

**Lumbosacral Backache**—Charles E. Ayres reviews the physical and roentgenological findings in 22 cases of lumbosacral backache, which show that the source of disability is undoubtedly in the lumbosacral joint, and his studies would lead to the conclusion that lumbosacral arthritis

is much more commonly the cause of back pain than has previously been recognized. The most effective method of dealing with this condition is the production of a bony ankylosis, according to the fusion method of Hibbs. Of the 22 cases in this series 21 were submitted to operation. The fusion operation is not accompanied by shock and is not a dangerous operation when done properly. Ayers also finds that congenital anomalies of the fifth lumbar vertebra are not uncommon. Sacralized lumbar vertebrae are frequently the cause of persistent backache and can be relieved only by ankylosis. The approach necessary for the fusion operation gives an excellent opportunity to examine the bony structure and should be performed in selected cases in which the x-rays do not corroborate the physical findings. In a few of Ayers' cases the spinous processes on one or more vertebrae had grown abnormally large so that in the erect position one of these spinous processes rested directly upon the one below it. Peculiar pain symptoms resulted with radiating pain to the sides. These were treated by removal of a portion of the spinous processes that caused the impingement. Lateral x-ray examination of the lumbosacral region is essential in arriving at a diagnosis of low back pain—*Boston Medical and Surgical Journal*, January 6, 1927, xcvi, 1.

**Recovery in a Case of Tuberculous Meningitis**—O. Wiese, a pediatricist who read of a cured case of this affection in a previous issue of the same periodical, relates a similar experience which happened in 1921 and which he had forborne to publish because it referred to a single patient with a disease called a hundred per cent fatal. The patient was a ten-year-old girl with multiple bone-joint tuberculosis who after a year of surgical management suddenly developed the typical picture of meningitis with tubercle bacilli in the cerebrospinal fluid and urine. The treatment, instituted on the fifth day of the disease, consisted in withdrawing 60 c.c. of spinal fluid and reinjecting 3 c.c. of the same into the buttock while 1 c.c. old tuberculin, 1 to 1,000, was thrown into the spinal canal. The child at the time was desperately ill, but slept quietly that night and the next day her condition was so much improved that there were no longer symptoms of meningitis. Upon her recovery it was found that she had developed a tuberculosis of the right kidney, for which nephrectomy was performed 5 months later. The general health at once improved and the hip and ankle tuberculosis showed a marked tendency to heal. In another five months the patient was discharged clinically cured and is at present in the best physical condition despite the fact that her home surroundings are unfavorable—*Muenchener medizinische Wochenschrift*, November 12, 1926.

the end of four or five days, the antrum is cleansed, and the upper angle of the dislocated lateral wall and the agger nasi is packed to keep the turbinates in contact with the septum. The packing is repeated every three days for three to five weeks. The adhesions should not be disturbed for three or four months, then they should be cut. The secret of a good result with this procedure depends upon the after care—*Boston Medical and Surgical Journal*, December 23, 1926, cxcv, 26

#### Transfusion Treatment of Typhoid Fever—

H. Schottmüller of Hamburg, at the close of a paper on this affection, recommends what he terms a new method of treatment. He takes from a recovered typhoid patient who has been free from fever for at least 3 to 4 weeks from a half to three-fourths of a liter of blood. The delay is in part to avoid the danger of a relapse, which has never been known to occur after the third week of convalescence. It is of course understood that as a blood donor the patient should be in excellent physical condition and free from all complications. The convalescent blood thus obtained should be used in special cases in which life is menaced, for example in intestinal hemorrhages, and for very early cases in which there is an opportunity for aborting the disease. The method is to all intent a blood transfusion and the blood should be typed and all other precautions taken which belong to ordinary transfusion. The motive for this treatment is partly the unsatisfactory character of blood-serum treatment and partly the accumulated knowledge of the past twenty years that full blood possesses antibacterial qualities. The author even suggests that if a typhoid convalescent is not obtainable a healthy donor would be substituted. No particular technique of transfusion is mentioned and the author only states that before transfusion he does not hesitate to abstract say 100 c.c. of blood from the patient in order to guard against overburdening the circulation—*Muenchener medizinische Wochenschrift*, October 15, 1926

**Some New Points in Oral Sepsis**—In connection with the effects of root-canal infections upon the body in such disorders as chronic myocarditis, arteriosclerosis, gastric ulcer, gall-bladder disease, and chronic arthritis, Anthony Bassler (*Medical Journal and Record*, January 5, 1927, cxxv, 1) points out that there are individuals in whom apparently a specificity in this respect develops and is handed down to subsequent generations. He thinks there is little doubt that much of the Mendelian law of heredity is operative in this particular. He adds that the tooth histories of 40 persons whose teeth were in exceptionally good condition for their ages showed that back to the third generation good teeth were the rule, and such departures as were met could be accounted for by lateral incursions in the main family strains. In explaining the effects of these

lateral incursions, there is really no reason to believe that the infants are born with infections, but instead that a predisposition to these infections is handed down. Of first importance are the matters of heredity and middle some cosmetic but destructive types of dentistry. Other factors are the effect of the endocrine glands upon the development of the teeth—the pituitary in the early days, the thyroid at adolescence, and the parathyroid from the twenty-fifth year on—and changes and variations of the blood calcium. Studies should be made along these lines so that medical men and dentists could formulate some simple clinical truths which would result in the prevention of loss of teeth and infection in teeth. It is not generally known that with apex infections, which are apparently causative of myocarditis, arteriosclerosis, and arthritis, a moderately low blood calcium commonly coexists, having been brought about by the deficiency of the parathyroids. A further point, which physicians as well as dentists seem not to be cognizant of, is that it is rarely true that a tooth which by the x-rays shows a sac-like darkened shadow figures very prominently as an etiological factor in the production of remote organic diseases, it is the nonsac-like types that are the more dangerous, inasmuch as the bacteria then have free access to the lymphatic and general blood stream, and the same holds true for the toxins that are readily absorbed into the body. The hemolytic and non-hemolytic streptococcal forms are decidedly the more common, while the most common of all the apex infections is the *Streptococcus fecalis*. Still another point to which Bassler calls attention is the tendency of amalgam fillings to become leaky, this should not be lost sight of in considering focal infections. Neither should it be forgotten that the mucous glands under the tongue, on the buccal surfaces, and on the gums may harbor infection, and that without showing swelling or setting up pus formation.

**Transmission of Scarlet Fever**—U. Friedemann and H. Deicher of the Rudolf-Virchow Hospital, Berlin, take up this subject jointly, Friedemann taking the general and Deicher the experimental end. The authors record the subject as highly important, for Czerny and von Sontagh, they say, are not satisfied that the disease is transmissible by contagion. They sum up the results of the labors of the Dicks and of Dochez in the recognition of the hemolytic streptococcus as the actual cause of the disease and think it remarkable that every one who has thus far gone over the work of the Americans is quite convinced of the truth of their claim. Some, however, assert that an ultramicroscopic virus is concerned, but this view has been brought into harmony with the streptococcus claim by conceiving that a mutation of the latter to the invisible form is possible. The only vulnerable spots in the streptococcus theory are the number and variety of the pathogenic streptococci and the fact that

## DR. CASPER PENDOLA—MARTYR

Recently in Brooklyn a tragedy occurred. Little six-year-old Joseph Caruso was lying ill. His father Frank was alarmed. The boy had been sick for two weeks without medical attention. Finally the father decided to call in a doctor. Dr. Casper Pendola was summoned and there, in this little Italian home, he made an examination of the child and saw at once that the boy was suffering from diphtheria and was close to death. Doubtless there was no way in which the child's life could be saved. The Klebs-Loeffler bacilli had been carrying on their devastating work too long. Perhaps an injection of anti-toxin, even at that late hour, might help and Dr. Pendola injected it. Through the night the boy grew worse. Crazy with anxiety the father watched. In the morning the whole family—the father, the mother Marie with the infant Edith in her arms, the nine-year-old sister Lena, the eight-year-old Josephine, the three-year-old Anna and the two-year-old Salvatore were all assembled in panic-stricken silence in the kitchen of the four-room flat where Joseph, stretched upon a cot near the stove, was fighting feebly for his life.

There was a rattle in the boy's throat. In the silence the ticking of a clock in the adjoining room was heard, otherwise there was no sound. In a little while the boy was dead. The ambulance surgeon who was called gave the infant one brief look and turning away said, "There is nothing to be done, the child is gone." "That other doctor killed him and I will kill him when he comes," the father cried. This was at half past ten in the morning.

Four hours later there was a knock at the door. "Keep quiet," the father said, "it is the other doctor. I will kill him." Dr. Pendola entered and as he came the father leaped for his throat in an effort to strangle the doctor with his bare hands. "You killed my boy," he shouted. "You thrust a needle into him and he died." There was a brief scuffle. They rocked back and forth across the room, crashing into a chair, which was splintered. They rolled on the floor locked in each other's arms. They staggered to their feet, they tripped over other furniture and there was a sound of swift-taken breath and the crack of broken wood. Caruso's hands were at the doctor's throat. The two men fought on struggling amid a tangle of chairs and bedclothing. Rolling free of it they fought on through an open doorway

into another bedroom, where Caruso again flung the physician upon the bed, at the same time snatching up a butcher's knife fifteen inches long. The knife was kept in the kitchen. How was it that the knife was there at the assailant's hand ready for use? Presently the tumult ceased. Again there was silence and Caruso came out of the bedroom and went to the kitchen sink and washed his hands. "Keep quiet," he said to the terrified mother cradling the crying infant in her arms. "I have killed him, say nothing." He put on his coat and hat and walked into the street. A little later the police came. Dr. Pendola lay upon the bed. His throat had been cut. He was dead. The young doctor, only twenty-seven years old, had given his life in the cause of medicine. All that science could do, he had done. All the skill and knowledge of the healing art had been brought to bear to save a hopeless case and his reward was assassination.

Any doctor going into such a home may become a victim of demoniacal ignorance, and yet just as the soldiers in an advance push on after their comrades have been shot down, the medical profession will continue in the pursuit of its high calling, in the alleviation of pain and suffering, in the great struggle against disease and death. It is not often that the ingratitude of patients manifests itself in so extreme and tragic a form. Yet ingratitude of some kind is oftentimes the only reward accorded to the doctor for his skill, diligence and self-sacrifice in following a high calling.

No less malevolent, no less unfounded, no less cruel, are the assaults made by patients on their doctors through the familiar medium of malpractice suits. It is a privilege and pleasurable duty to stand between them and the unjustified assaults which their ungrateful patients so often launch against them.

Dr. Pendola was a true martyr of the medical profession, but the blood of the martyrs is the seed from which renewed inspiration will spring. The prevention of such a tragedy as his will come from a broader education of the people in medical subjects, under the leadership of family doctors.

Especially is this education needed in the case of foreigners to whom a hypodermic injection appears to be a poison, and a cut an unjustifiable assault.

**Preoperative and Postoperative Treatment in Patients With Gastric and Duodenal Lesions**—R Franklin Carter gives detailed instructions for the more careful preoperative and postoperative treatment of this class of patients as a means of further reducing the mortality of the operative period. In the preoperative period, if there is evidence of obstruction with accumulation of foreign material, repeated washings are indicated with solutions to which hydrochloric acid (20 minims to the quart) has been added. These should be given two or three times a day for two or even three days before operation. If there is absence of free hydrochloric acid, this should be supplied by mouth. In the peculiar type of anemia accompanying gastric lesions, transfusions, moderate in amount and repeated two or three times in the course of two or three weeks, reduce the danger of death from shock, infection, and cardiac failure. Except in extreme emergency, operation for a gastric lesion should not be performed until knowledge has been obtained of the blood sugar, chlorides, and carbon-dioxide combining power. If the latter is below 40 it indicates acidosis and should be combated by glucose 3 per cent and sodium bicarbonate 1 per cent, in 800 c c doses, until the carbon-dioxide combining power reaches 50. High carbon-dioxide combining power indicates alkalosis, and is counteracted by giving chlorides in 2 to 4 per cent solution, in doses of 1,000 c c. In those who have been under the Sippy routine, the alkali should be discontinued one week before operation. In the presence of obstruction sodium chloride is the most effective agent. Catharsis should be avoided in the 24 hours preceding operation. Feeding in non-obstructive cases is continued until 8 hours before operation. After operation, if respiration and pulse are regular, the patient should be kept under morphine for the first 8 hours. A record of the pulse should be taken every hour for 6 hours, as thus postoperative hemorrhage may be suspected before it reaches a dangerous stage. After the first 4 hours water may be given by mouth with sugar or some flavoring. On the second day the fluid intake should be 2,000 c c, the total food intake 400 calories. Recovery depends largely upon the nursing, as frequent and concentrated foods in small amounts must be urged upon the patient. Frequent blood analyses insure against unexpected acidosis or alkalosis. The fluid intake should be supplemented by subcutaneous saline as glucose cannot be used daily since it is apt to cause inflammation, nor should rectal feeding be employed. Hemorrhage, vomiting of bile after 18 hours, and delayed shock, are treated by frequent lavage with water at 100°F. In postoperative obstruction the decision to operate may be placed without equivocation on the blood findings alone. Here replenishing of the chlorides is of first importance, though operation should never be delayed with a carbon-

dioxide combining power above 90 and a chloride above 0.35. A carefully planned simple diet is outlined for the convalescent and follow up period—*Surgery, Gynecology and Obstetrics*, January, 1927, xlv, 1.

**Electrical Treatment of Obesity**—Franz Nagelschmidt, writing in *Physical Therapeutics*, January, 1927, vol xiv, 1, points out that, aside from race peculiarity, obesity is always a symptom of disturbed metabolism. It is unscientific to expect that any method will cure every case of obesity. Rational treatment for obesity must consist first in a diet which restricts fat, carbohydrates, and liquids to a certain degree, secondly, it must alter the metabolism, i.e., essentially the internal secretions or their vegetative control. This is done by muscular work well directed and slowly increased (electrorhythmic) and by laxatives, by the treatment of certain organs (for instance diathermy to the liver, x-ray therapy to the thyroid, stimulating irradiation of the ovaries, diathermy to the ovaries and testicles, diathermy to the pancreas), by psychic therapy, strengthening the will power, by improving the circulation by means of diathermy and the electrorhythmic current. Finally, the position therapeutically reached must be maintained by regulating the mode of living—moderate diet, regular exercise and fresh air, sport, moderation in drinking, especially alcohol. Since obese people dislike to do physical work and often are unable to do it, the electrorhythmic current represents, next to diet, the most important factor of the therapy. The author has devised a new apparatus for supplying an alternating current which is subject to regulation in all its characteristics—tension, intensity, number of periods, duration of current flow. With a dry element current as supply there are sixty alternations a second. The clinical application of this new current affects a variety of fields. Employed without interruptions, the current is suited for producing electrical sleep, electrical narcosis, and electrical anesthesia. With rhythmic interruption, it serves for diagnostic purposes, applied to single muscles or parts or groups of muscles, or to nerve points. It may be used in paralysis or muscle debility—after operations, after confinement, in infantile paralysis, fractures, etc. Applied to the whole body it is useful for exercise and for the treatment of heart diseases, to promote reconstruction and in the treatment of disturbed metabolism, especially of obesity. In relatively sound obese patients a course of twenty-five daily sittings of one hour's duration is usually sufficient. The general technique calls for an equal performance by the whole musculature of the body. The results are tabulated for 300 patients treated in this way, those who had 35 sittings or more lost an average of 12.6 per cent in weight.

confirmed the diagnosis of the defendant. The mother was advised that the child was suffering from an acute dilatation of the heart due to toxemia. The specialist ordered a stimulant of camphor and oil and digitalin, which were administered hypodermically. At about 8 P M on December 23rd the defendant physician again returned to the home of the patient and hypodermically administered digitalin. The physician remained with the child for about a half hour, at which time the child seemed to be much better. However, there was a pallor over the child's body, his face and lips were still blue and the doctor stated that the child was kept alive by the use of the whiskey stimulant. At about 9 A M on December 24th the physician again called on the child, found his pulse weak and rapid, respiration labored and the body cold. No change in medication was ordered. He again returned at about 4 P M of that afternoon accompanied by the consultant. Further administration of camphor and oil and digitalin were ordered. A nurse had been procured and was in attendance upon the child. The defendant physician called on the child at about 10 A M on December 25th. The child at this time appeared to

be very weak with a fairly good pulse. The nurse, with the father's permission, had been permitted to be away over the holiday. At about 4 o'clock of that afternoon the defendant was sent for and upon arrival at about 4 45 P M he found the child dead. The death certificate was made out by the defendant physician, the cause of death being given as acute myocarditis due to diphtheria.

The parents thereafter complained of the defendant's treatment to the Health Commissioner who summoned both the parents and the physician before him and had a private consultation with them. The defendant was advised by the Commissioner that he had not complied with the sanitary provisions in that he failed to take a culture, he was further advised that the death of the child was not due to the treatment upon his part.

After the action had been pending for some time and after further inquiry into the matter by the plaintiff's attorney and they being satisfied that the death of the child was unavoidable and not due to any negligence or carelessness upon the defendant's part, they consented to the discontinuance and termination of the action.

---

## BURN IN ADMINISTRATION OF ELECTRICAL THERAPY

In this action it was charged that in the treatment of the plaintiff for the illness from which he suffered, the defendant physician had used certain electrical appliances and electrical machinery, that the use of the same was carelessly and improperly done by the physician so as to cause the plaintiff's arm and hand to be burned, with a subsequent infection, rendering the patient ill, preventing him from following his usual occupation, causing him to be treated by other physicians and to expend monies in his attempt to be cured of the injury claimed to have been caused by the defendant. In this action he sought to recover damages for these injuries.

The plaintiff in this action, a middle-aged man, called upon the defendant physician complaining of nervousness, and after examination by the defendant it was decided to administer electrical treatment for the patient's condition. In preparing for the administration of the electrical therapy, the patient was brought into the electrical treatment room, seated in a chair alongside of a Wappler machine. The de-

fendant's associate, a physio-therapy technician, then proceeded to administer the electrical treatment. The chair was equipped so that the current would pass through the body of the patient, through the chair, thus forming a ground. The buttocks were bared and likewise the arm. To the arm was attached a metal wristlet. This method of electrical treatment is described by the defendant physician as auto-condensation. The patient was first treated on February 10th and then every other day until about March 1st, like treatment being administered to him each time that he called. The next seen of the patient by the physician was March 15th, at which time the patient called upon the defendant and exhibited his arm where there appeared a superficial burn at the place where the wristlet had been attached to the arm. No treatment was rendered by the defendant physician at this time and this was the last that the patient was seen by the physician.

The trial of this action resulted in a verdict in favor of the defendant.

## DIPHTHERIA CAUSING ACUTE MYOCARDITIS AND DEATH

An action was brought by a father as the administrator of his deceased son. He claimed that in the month of December he engaged the defendant as a physician to attend his son and to cure him of diphtheria from which he was then suffering. That as such physician the defendant undertook to attend and care for the son. It is charged that as such physician he did not use proper care or skill, that he failed to take a culture in due and proper time, that he failed to administer an anti-toxin in due and proper time and negligently prescribed and administered to the deceased patient. That by reason of the negligence of the defendant physician the patient did not recover but died from diphtheria. \$10,000 damages were asked for the death of the patient.

The family of the patient were known to the defendant physician for about three years and during this time had attended and treated various members of the family for different ailments.

At about 6 P. M. on December 16th, he was called to attend the deceased, a boy about eight years of age. The mother gave him a history that the child had an attack of tonsillitis. Upon examination of the child's throat the physician found a condition of acute tonsillitis and prescribed citrates and salicylates. The mother stated that the child had been sick for several days and at the time of his examination had a temperature of 101°. In the preceding May and June the defendant physician had seen this child and had treated him at that time for an attack of tonsillitis and had also advised the performance of a tonsillectomy. In the preceding year the child had also had attacks of tonsillitis for which the defendant had treated him. These attacks lasted from three to four days. At the examination made on December 16th the pulse was found to be rapid and the throat congested and a diagnosis made of tonsillitis. From his examination the defendant found that only the tonsils were infected and there was practically no membrane at that time. He called again on December 17th to see the patient and found that his condition was markedly improved, the temperature was then 100°, pulse and respiration had come down to almost normal and the child looked much better. He advised the mother to keep the child in bed and to continue the medication.

On December 18th he found the pulse and respiration normal, but there was a slight increase in temperature and on examination of the throat he noticed a white spot on the right tonsil. This examination was made at about 10 A. M. He called the mother and showed her the white spot upon the tonsil. He did nothing further at that time, but stated that he would

call again in the afternoon and give the child 12,000 units of anti-toxin. During the afternoon the physician returned and administered 12,000 units of anti-toxin. He gave the mother instructions to have the child gargle his throat with glycothymoline listerine. The physician called upon the child on December 19th and on examination of the throat found that the white spot had disappeared, the tonsil condition was also clearing up, the pulse and respiration were normal. He again advised the mother to continue the medication and gargle as previously instructed and that the child be kept in bed. No further anti-toxin was administered on this visit. The child was again visited on December 20th and 21st, when the condition of the child was found to be the same. On each of these visits the throat was examined, the temperature, pulse and respiration were taken and the medication previously prescribed was ordered continued. No further anti-toxin was administered on either of these days. On December 21st a report was made to the Board of Health by the defendant physician that the child was suffering from diphtheria and that he was attending the child for such condition. During his treatment of the child no culture was made by the physician. On December 22nd he had ordered a stimulant of whiskey to be given to the child by way of mouth, a teaspoonful in water every two or three hours. When the physician called at the boy's home on December 23rd the father stated that he objected to the use of anti-toxin as some doctor had told him that anti-toxin damages the heart and that the boy was dying because anti-toxin had been given him. At this time the physician examined the child's throat, took his pulse and respiration and found that all were clear. The mother stated that the child wanted to go downstairs for lunch, but the doctor advised against this and stated that the child should be kept in bed. When leaving the patient's home on this visit he told the mother that he would not see the child on the following day, which was Sunday, but would call in to see him on Monday, December 25th.

On December 23rd, at about 3 P. M. a telephone call was received by the doctor from the patient's home that the child's face and lips were blue. He immediately went to the home of the patient, examined him and found an acute myocarditis. A hypodermic of two grams of camphor and oil was administered. The pulse at this time was rapid and weak and the respiration was labored. The child was surrounded with hot water bags and blankets and kept in bed. The defendant physician then called a heart specialist in consultation. The specialist examined the child thoroughly and

ary We don't try anything new It is almost impossible to get any place with it You have got to have it debated for years, you have got to make arguments about it, gather people together, make a great deal of publicity for it, no matter what it is It took us nearly eighteen years to enact the Mothers' Pension Law Nobody who is in the Legislature or who is out of it would seriously suggest that we go back to the old method We were ten years getting the Workmen's Compensation Law, and the very men who opposed it most vigorously were the ones who afterward declared that under no circumstances would they ever think of returning to the old condition

"We will have to get away from the small unit in time The state is growing away from it, it is getting too big Distance has been annihilated by the automobile and by the speedy trains, by direct communication with the telephone, and now the radio We are all neighbors together

"Where would the City of New York get off if they had five health departments, one for each borough? It is perfectly all right to have five sewer departments and five departments of public works, or five departments of highways, or five departments of public buildings, because conditions may not be the same in the different boroughs A sewer constructed on Manhattan Island may be entirely different from one constructed in the Borough of Queens But certainly, scarlet fever and measles are the same, no matter where it is They can not divide that by borough lines You can not have a Kings County brand of tuberculosis and a Bronx County brand So that public health work in its very nature has got to be cared for in the largest unit you can put it in If you look at the structure of the Department of Health of the state even as far back as the time of its organization, that must have been an important consideration in its make-up, because, outside of the city of New York it takes a full and complete control notwithstanding the local agencies already set up

"I do not think that you can figure this question of public health on a dollars and cents basis I think that is the most foolish, most short-sighted policy that the state could adopt Preventable sickness and preventable disease is the cause of a great deal of crime, and look how dearly we pay for that in after years by our failure to make adequate appropriation to check at the right time What happens when the sick person becomes a public charge? Think of the misery and privation and disease and sickness that follows from a failure on the part of the state to take the proper view and preventable steps at the critical period

"I do not believe this state spends anything

near the money it should in the interest of public health, taking the state as a whole We are putting more money every year into the operation of a canal that nobody seems to have any use for We have spent an awful lot of time trying to induce men to build canal boats to operate on the canal I am pretty sure we are spending nearly as much for the conservation of wild life in the state and the preservation of the forests as we are directly for the promotion of the public health

"Now certainly everybody is for health and for education The only thing to do is try and get it going right, try and get it properly understood Our greatest problem here is to have our people understand what we are trying to do

"Now the old-fashioned health idea was that the fellow came around and stuck the red or yellow flag on the door and locked everybody in and it was all done That is not the state's idea of public health today Our own department reflects it It is the clinical laboratory service, the nursing service, the educational program for the prevention of disease, and the opportunity for better treatment

"There has been a drift towards county administration of certain health matters, but that drift has been by the lack of proper control, it is haphazard, it is not performed in a satisfactory way, but the drift indicates that the time is not far away when the question of public health will have to be a county function if it is to be properly and scientifically, and incidentally, let me say, economically managed, because the \$10 note for public health that is wasted is a double waste We can lose \$10 on the building of a road, but we can not afford to lose it on either education or public health, because you can not make it up When it goes, it is gone forever So that economy will in time suggest to us that this larger unit be adopted

"I hope that from the meeting today will grow something worth while to the state I hope that the members of the boards of supervisors from other counties will not be discouraged because it has been brought out in the meeting that a large amount of private funds have helped make Cattaraugus County so successful

"I can speak for the state and for the temper of its government. If we found the different counties a little bit more active and a little bit more willing, it is entirely possible for the state to be a little more generous But it is a bit discouraging to the state to think that no county wants to take advantage of the state's subsidy, for so important a function as the public health And bear in mind this, that you are paying part of the subsidy that is go-

# NEWS NOTES

## THE GOVERNOR'S HEARING ON COUNTY DEPARTMENTS OF HEALTH

On February 24th, in accordance with a previous announcement, the Governor gave a hearing to representatives of about 30 county boards of supervisors, officials of the Department of Health, the Medical Society and certain lay organizations interested in public health, on the question of the creation of county health units. There has been a statute on the books for about five years, authorizing the creation of county health units and offering, on the part of the state, to reimburse the counties 50 per cent of the amount of money expended annually in conducting such health units, but up to the present only one county—namely, Cattaraugus—has availed itself of this opportunity, and the Governor was eager to discuss with persons whom he considered informed on the matter, why the offer had not been more generally accepted.

Among those speaking, at the time, was President George Fisher, who said that the State Society was appreciative of the interest the Governor had shown in public health activities, and that he wished the Governor to understand that the State Society is willing to consider ways by which it might cooperate with the proper authorities in promoting conditions of health in the state.

Mr Homer Folks, Secretary of the State Charities Aid Association speaking from the standpoint of the County Tuberculosis and Public Health Committees said

"The funds for county Tuberculosis Committees are secured through the sale of Christmas seals organized and directed by these county committees amounted last holiday season to \$515,000—a very large addition to the resources available for health work throughout the state. Most of the county committees are able to employ full-time executives, some of whom are nurses who actively promote a good health program for the entire county. They assist in the establishment of county tuberculosis hospitals, in promoting public interest and assistance in the management of such hospitals, in securing clinics through which the right patients are found for hospital care, and in securing home assistance and medical supervision for patients going back to their homes after hospital care.

"The Secretary of the County Tuberculosis Committee is, however, in most cases, the only representative of any organization pushing a county-wide health program and with the limitations of a voluntary agency there is ur-

gently needed a strong county-wide general health authority.

"These voluntary county health committees would gladly follow the lead of an official county health agency. They want it and would gladly cooperate with it and assist it in every way. They do the best they can under present circumstances but their usefulness is limited by the absence of a corresponding public health authority.

"The voluntary health agencies of the state have already gone on a county basis through sheer force of circumstances and as the only method of getting results. They urge that public health work take a similar course and pledge to it their cooperation, and ask from it authoritative leadership."

Doctor Matthias Nicoll, Jr., State Commissioner of Health, said that the state had gone practically as far as it could in furnishing health protection to the people of the state without securing larger units of public health administration. He strongly advocated the county as such a unit. He also advocated amendments to the existing law, which would place a larger measure of responsibility and authority in health matters upon Boards of Supervisors. He said that Cattaraugus County was a proving ground for health work.

Governor Smith summed up the situation in an informal twenty-minute address, from which the following abstracts were taken.

"We have here the fundamental question that this state is constantly being confronted with, and that is that the day must come when we have to get away from the old-fashioned government that was set up by our law and in the Constitution when it took a whole day to get here from New York.

"Now consolidation is popular. We have just consolidated some 150 boards and commissions in the state government, and, as a result yesterday and two weeks prior to yesterday, I was able to sit around a table in this room here with the responsible head of every branch of the government in this state, with the exception of the Comptroller and the Attorney-General who were elected with duties clearly defined in the Constitution and not of any administrative character.

"Dr Nicoll said something about sticking to the old idea, the old town, and the old village idea. Of course, throughout the length and breadth of this land, this state has the unenviable reputation of being absolutely reaction-

"It has happened that when a local public health organization has become involved in a dispute with the doctors of the district, an investigation has been made by the parent society, which, of course, has upheld the action of the lay society, and in this way has perpetuated erroneous methods of work. This will be eliminated by the newly-formed committee on Public Relations of the State Medical Society which is composed of representatives of physicians as well as laymen."

Dr. Farmer referred to the tendency of the leaders of voluntary organizations to claim the credit for the progress attained in any line of work in which they may be engaged. "This may be necessary," he said, "in order to make good reports on whose basis funds may be obtained. However, any one who studies the activities of medical societies will be struck with the number and kinds of the public health work of the doctors. The Syracuse Academy of Medicine is for example a scientific body composed entirely of physicians, and yet a consideration of local problems in public health has occupied a large proportion of its deliberations. Nearly all the time of many meetings have been devoted to the practice of civic medicine. Among the public health activities promoted have been pure milk supplies, a contagious disease hospital, meat inspection, a hospital at the County Home, dental clinics, and medical school inspections."

Dr. Farmer emphasized the necessity that physicians should not merely follow the steps taken by voluntary organizations, but should assume the leadership and direction of the medical work, and be members of the boards of directors of the voluntary health organizations, and should direct their medical activities. Physicians are rapidly acquiring the ideal attitude of leadership in all public health work.

Dr. Farmer described the plans of the Public Relations Committee, especially in the promotion of county departments of health, and said that there was need for such a committee in every county society.

Dr. Wilmer Kreusen, Commissioner of Health of Philadelphia, spoke as a physician who is trying to treat the public as a patient, and who is a practicing physician specializing in community health. He described his intimate relations with over twenty voluntary health agencies of major importance. Among them were the following groups:

- 1 Visiting Nurses' Society
- 2 Health Council which sells the Christmas Seals
- 3 Child Health Association
- 4 Heart Association
- 5 Cancer Society
- 6 Dairymen's Council
- 7 Housing Association

- 8 Red Cross
- 9 Federation of Charities
- 10 Hospital Association
- 11 Day Nurseries
- 12 Emergency Aid Society, working largely among crippled children
- 13 Women's Clubs, especially the Women's Auxiliary of the State Medical Society
- 14 Social Workers
- 15 Psychiatric Clinics
- 16 Playground Association
- 17 Boy Scouts
- 18 Mothers' Clubs
- 19 Mouth Hygiene Association
- 20 Commission on pneumonia
- 21 Dispensaries

Dr. Kreusen said that he found a plan of great value to be that of inviting the organizations to meet in the offices of the Department of Health, for in that way he kept in close touch with them.

Dr. Kreusen also emphasized his approval of Dr. Farmer's plan that every county society should assume the leadership in public health work, and should have a committee on Public Health Relations modelled after that of the Medical Society of the State of New York.

Dr. S. B. English outlined some of the sources of disagreements between the physicians and the voluntary agencies, especially the New Jersey State Tuberculosis League, which is like the New York State Charities Aid Association. The League has a budget of about \$250,000. It staged a demonstration of examining factory laborers for tuberculosis. It sent about 3,000 letters to the family physicians of those who were examined, and received very few replies. The League interpreted this failure to reply to be a lack of interest on the part of the physicians, and it planned to set up its own clinics. Here are all the elements for misunderstandings on the part of both the voluntary workers and the physicians. The remedy is friendly consultations such as those afforded by a committee on Public Relations.

Dr. English developed the thought that doctors wanted to treat only the sick, and that the sicker the case, the more interest the doctor took in it. The reason is largely that the doctor can give orders to a sick patient and the nurse and the family, and can get his orders carried out. The doctor cannot order a well patient, or a voluntary health organization. He must spend much time in patient explanation and persuasion for which he gets no financial fee and from which he sees few immediate results. But in every county society there is some doctor who is specially fitted to deal with the voluntary organizations. Let him advise them in the name of the society, and let the rest of the members support him.

Dr. James S. Green, emphasized the need of

ing to Cattaraugus, and every county ought to be looking after some part of it for themselves, because it will pay not only in dollars and cents from the state but it will pay in the return of public health and better citizenship and a more vigorous people in the county where the money is properly and carefully expended

"Now that sums up all I have to say, except

to thank all who came here today and if you have any desire to formulate yourselves into any kind of a committee for the promotion of what we have been talking about today, I will be glad to give it my active support, all the time I can spend at it, and help it in every way that can be done through the Executive Department"

### TRI-STATE CONFERENCE

A meeting of the Tri-State Conference of representatives of the Medical Societies of New York, New Jersey, and Pennsylvania was held on Saturday, February 26, in the Hotel Pennsylvania, New York. Dr George M Fisher, President of the Medical Society of the State of New York, presided, and the conferees were guests of the Medical Society of the State of New York at a midday luncheon. Fifteen members were present, as follows

From the Medical Society of the State of New York

George M Fisher, President, Daniel S Dougherty, Secretary, Joseph S Lawrence, Executive Officer, Frank Overton, Executive Editor, N B Van Etten, Past President, James E Sadlier, President-Elect, and Thomas P Farmer, Past Commissioner of Health, Syracuse

From the Medical Society of New Jersey

James Green, President, J B Morrison, Secretary, H O Reik, Editor, and S B English, Superintendent of the Glen Garden Tuberculosis Sanatorium

From the Medical Society of Pennsylvania

A C Morgan, President-Elect, Frank Hammond, Editor, and Wilmer Kreusen, Commissioner of Health, Philadelphia

From the American Medical Association

Dr Wendell C Phillips, President

Dr Fisher, in opening the Conference, spoke of its increasing importance as a medium for the exchange of ideas on administration topics, and mentioned the recent appointment of two new committees of the Medical Society of the State of New York—that on Public Relations and that on Cardiac Diseases. He introduced as the principal speaker Dr Farmer, who is Chairman of a sub-committee of the Public Relations Committee

Dr Farmer addressed the Conference on The Relations of Voluntary Agencies to Physicians. "This subject," he said, "is the object of consideration by the Public Relations Committee. There is no doubt about the value of voluntary organizations to physicians in promoting the same aims for which physicians work, but probably most physicians recall

their infrequent dysfunction rather than the great good which they do

"While physicians are leaders in public health movements, yet the execution of their plans requires the assistance of voluntary organizations in order to raise money and create public sentiment. While friction and misunderstandings have resulted when voluntary organizations have acted without consulting the practicing physicians, mutual helpfulness has followed the recognition of the peculiar fields of each group of organizations. There is a danger to lay organizations themselves when they have misunderstandings with physicians. They cannot work efficiently unless their medical bases are sound, and if the bases are not fundamentally correct, financial gifts from their supporters will cease. Happily the major problems in the differences between the lay organizations and the medical societies are practically solved, although many physicians are not yet aware of the new agreements between the two groups of organizations

"Voluntary organizations have tended toward the promotion of state medicine. This was inevitable when physicians themselves neglected to put to practical use the newer discoveries in preventive medicine and to develop plans to create public sentiment in favor of accepting the services of family physicians in preventive medicine. But family physicians are now awake to the necessity and opportunity of practicing preventive medicine, and treating sickness in the incipency and pre-clinical stage, and even promoting a hygienic mode of life in which even the tendency to sickness is minimized. Physicians in private practice can do preventive work far better than any set of officials paid by the State

"One source of misunderstanding has been the expectation that busy doctors will make reports and answer questionnaires for which they see no direct benefit. Surveys based on idealistic standards have been interpreted to indicate the doctors have been uncooperative with patients seeking advice in preventive medicine. The truth is that doctors have always been ready and anxious to have their patients profit by their advice

ples from the far West as well as rarer cities of the East. It is an collected in New York and therefore f the exhibits are from this city that subsequent exhibitions will at a larger representation from rofession can be gotten together tors can find time to acquire the

skill to do the things shown in the Academy of Medicine at this exhibition, proves a most important fact that makes for health and contentment in life. Every man and woman should find a hobby to ease the routine of business and of home living. And this hobby should, at least, have an absorbing interest and preferably should demand a creative effort."

of the Committee on Legislation states, as far as he knows, the general trend of the Legislature is against passing the Chiropractic Bill

Dr Gitlow submitted the Report of the Building Committee. The matter of meeting in the Professional Office Building is in abeyance because no building is going on there at present. Another place that could be purchased has been suggested. The Committee invites discussion by the members as to the possibility of purchasing a building. The President referred the Report to the Comitia Minora, which is to report back to the Society.

Dr Weitzner, for the Social Committee, outlined the purpose of the Committee and its plans for the year. He announced that the Committee has arranged for a Beefsteak Dinner to be held on Monday evening, February 28th, at Ebling's Casino, and appealed to the members for their cooperation and attendance at this dinner.

Dr Landsman introduced the following resolutions which were carried:

"WHEREAS, The Bronx County Medical Society having sustained a severe loss in the death of its honored associate, Philip Rifkin, M D

"Resolved, That the Bronx County Medical Society record the sense of its loss in the death of Dr Rifkin and that a minute thereof be placed on the records of the Society, and be it

"Further Resolved, That a copy of these resolutions be transmitted to the family of our departed member."

The Scientific Program then proceeded as follows:

### PAPERS

1 "Periodic Health Examination Service for High School Children," I H. Goldberger

2 "Backache from an Orthopedic Standpoint," Samuel W. Boorstein

3 "The Diagnosis, Pathology and Treatment of Osteomyelitis," Frederic W. Bancroft

Dr Bancroft's Paper was discussed by Drs Henry Roth, J. Lewis Amster, L. Miller Kahn and Samuel W. Boorstein

I J. LANDSMAN, M D, Secretary

a Public Relations Committee to guide the enthusiasm of the workers of the voluntary health organization

Dr J S Lawrence, Executive officer of the Medical Society of the State of New York, said that in the past the opinion of public health leaders has been that practicing physicians are not good health officers. The modern idea is that a health-officership is a specialty in the practice of medicine, and that the closer the health officer is to the practicing physicians, the better it is for the department of health, the physicians, and the public. Dr Lawrence enumerated the list of about fifteen voluntary health agencies with which the State Medical Society is in close touch.

Dr J B Morrison, Secretary of the Medical Society of New Jersey, said that voluntary agencies are here to stay because they do an indispensable work. Physicians must agree with them regarding their respective fields of work. The agreement could come through a public relations committee.

Dr James E Sadlier, President-Elect of the Medical Society of the State of New York, expressed optimistic views regarding the development of cordial relations with voluntary health organizations. He said that every county society had the medical talent to advise the lay societies and guide their work to their satisfaction as well as to that of the physicians.

Dr Sadlier also emphasized the need of informing the people regarding cancer, and said that he had planned to give much of his time to that activity in his home county of Dutchess.

Dr H O Reik, Editor of the *Journal of the New Jersey State Medical Society*, said that there was a plan to organize a State Association composed of all the local health associations of the State of New Jersey. He also said that the State Medical Society was planning to organize a Woman's Auxiliary along the lines which had proved successful in Pennsylvania.

Medical bills pending in the State Legislatures were briefly described. Dr Reik said that there were two important subjects before the New Jersey Legislature.

1 Separate boards were proposed for the examinations of candidates for medical licensure—one board for regular practitioners of medicine, one for chiropractors, one for naturopaths, etc. This bill had little chance of passing.

2 An anti-rabic bill, sponsored by the State Department of Health, providing that dogs should either receive the anti-rabic inoculations, or be kept at home or on a leash.

Dr Reik distributed samples of literature on these two subjects prepared by the State Medical Society for popular information.

Dr Frank Hammond said that the important medical bills before the Pennsylvania Legislature were those relating to a single board of medical examiners, and several on Workmen's Compensation.

Dr Lawrence reported that the successful passage of the Medical Practice Act last year by the New York Legislature had left comparatively few medical bills to be considered. Bills are pending providing for increased State aid to counties doing public health work and county activities.

Dr N B Van Etten, Chairman of the Special Committee on Nursing of the Medical Society of the State of New York, talked informally on practical means of training bedside nurses, and suggested that the text book training in such subjects as anatomy, physiology, and bacteriology be given in a three-months course before the pupil enters the training school. This plan will allow the nurse to give all her time to gaining practical experience at the bedside, and will enable her to graduate after a course of two years.

There followed an animated discussion of the training of nurses, and all agreed that the acute need is now that of providing nurses to give ordinary bedside care to sick people.

Dr Wendell C Phillips, President of the American Medical Association, spoke of the changing conditions in the practice of medicine. He said that a generation ago all the medical teaching concerned the fully developed stages of diseases. But now the teaching must include the recognition and treatment of diseases in their incipency, possibly before patients are aware of their existence. The new point of view is not that of sickness, but of health.

Dr Phillips spoke of the leadership of the American Medical Association in the newer methods of the practice of medicine, and concretely of *Hygiea*, the medical journal for laymen. While *Hygiea* has a circulation of 50,000 yet it is widely copied by the newspapers, and its articles reach millions of readers. One result of the educational work is that women's clubs usually refuse to listen to lecturers on anti-vaccination, anti-vivisection, and similar anti-medical talks.

Dr Phillips warned the physicians that the people were demanding protective and preventive medicine, and are inclined to force the establishment of those forms of practice by the State. Physicians must meet this condition by preparing themselves to practice preventive medicine.

The Conference voted to hold its next session in Scranton, Pennsylvania, some time during the month of May.

## THE AMERICAN COLLEGE OF PHYSICIANS

The American College of Physicians held its eleventh Annual Clinical Session during the five days, February 21-25, in Cleveland, Ohio, with about 2,000 physicians in attendance. The College of Physicians is to the internists in medicine, what the College of Surgeons is to the surgeons. The College of Surgeons is an older organization and has developed the system of standardization of hospitals throughout the country. However, the College of Physicians is in close touch with the College of Surgeons, and has representatives on its committees on hospital inspection and approval. It seeks to raise the standards of medical service in hospitals to an equality with those of the surgical wards. If a member of the College of Physicians later takes up surgery, his membership is transferred to the College of Surgeons and vice versa. While the qualifications for membership in the College of Physicians are less susceptible to exact measurement than those in the College of Surgeons, yet they are based on a demonstration of superior skill in the practice of internal medicine. Membership is an honorable recognition of a physician's superior ability and attainments as an internist.

The College of Physicians plans its programs so that its members may see new methods of medical practice demonstrated in clinics and in hospital wards. The College especially aims to reach the younger men who do not have the opportunities for frequent attendance on clinics and demonstrations.

The plan of the program of the Cleveland meeting was that the mornings were devoted to clinics, and the afternoons and evenings to the reading of scientific papers before the whole assembly of physicians. The exercises of the convocation of the College and the reception of new members were held on Friday evening, when the President, Dr Alfred Stengel, of Philadelphia, gave the Annual Presidential Address. A banquet was held on Thursday evening.

Fifteen clinics were scheduled every morning in the hospitals of the city, some of which were subdivided. The Medical School of the Western Reserve University did the unusual thing in arranging clinics by the departments of anatomy, physiology, histology, and biochemistry. Anatomy clinics were given on the practical subjects of the growth of children and the pathogenic tendencies of anatomic variability. The Department of Histology and Embryology demonstrated relation of the tubular embryonic heart to the cardiac patient. The Department of Physiology showed moving pictures of the mammalian heart and a simple

method for the registration of heart sounds, and demonstrated studies in respiration. In biochemistry there was shown the separation of hydrolytic products of proteins and the direct observation of the glomerular circulation in the frog. It is refreshing to find that the departments of medical study usually classed as pre-clinical were of direct interest to physicians engaged in the practice of bedside medicine.

Admission to the clinics was by cards which were given out only to the capacity of each clinic room. Some of the clinics were repeated.

The afternoon sessions consisted largely of symposiums. Among the subjects were diabetes, diseases of the heart and blood vessels, the gall bladder and liver, pediatrics, and the central nervous system. The subjects of the evening sessions were of a more general nature, and each program consisted of only two papers.

The names of the following physicians from New York State appeared on the program.

Dr Harlow Brooks, New York, Past President of the College, and a present member of the Regents of the College.

Dr W D Ayer of Syracuse, paper on paralytic poliomyelitis, with results of serum therapy.

Dr Walter A Bastedo, New York City, paper on digitalis therapy.

Dr Frank B Cross, Brooklyn, paper on the recognition of carcinoma of the rectum and colon.

Dr Charles S Danzer, Brooklyn, paper on therapeutic procedures in pleural effusions.

Dr Allen A. Jones, Buffalo, paper on coronary thrombosis.

Dr David Marine, New York City, paper on iodine in the treatment of goiter.

Dr P D McMasters, New York City, paper on urobilin, its physiology and pathology.

Dr C F Martin, Dean of the Medical School of McGill University, was elected president. New Orleans was named as the place for the next meeting, with Dr J H Musser, Jr, Professor of Medicine in Tulane University as chairman of the program committee. Tropical diseases will be the general topic of the meeting.

Any physician is welcome to attend the sessions. It is to be hoped that many physicians of New York State will attend the sessions in New Orleans and will find attendance at the meetings a happy way of combining business and pleasure.

a Public Relations Committee to guide the enthusiasm of the workers of the voluntary health organization

Dr J S Lawrence, Executive officer of the Medical Society of the State of New York, said that in the past the opinion of public health leaders has been that practicing physicians are not good health officers. The modern idea is that a health-officership is a specialty in the practice of medicine, and that the closer the health officer is to the practicing physicians, the better it is for the department of health, the physicians, and the public. Dr Lawrence enumerated the list of about fifteen voluntary health agencies with which the State Medical Society is in close touch.

Dr J B Morrison, Secretary of the Medical Society of New Jersey, said that voluntary agencies are here to stay because they do an indispensable work. Physicians must agree with them regarding their respective fields of work. The agreement could come through a public relations committee.

Dr James E Sadler, President-Elect of the Medical Society of the State of New York, expressed optimistic views regarding the development of cordial relations with voluntary health organizations. He said that every county society had the medical talent to advise the lay societies and guide their work to their satisfaction as well as to that of the physicians.

Dr Sadler also emphasized the need of informing the people regarding cancer, and said that he had planned to give much of his time to that activity in his home county of Dutchess.

Dr H O Reik, Editor of the *Journal of the New Jersey State Medical Society*, said that there was a plan to organize a State Association composed of all the local health associations of the State of New Jersey. He also said that the State Medical Society was planning to organize a Woman's Auxiliary along the lines which had proved successful in Pennsylvania.

Medical bills pending in the State Legislatures were briefly described. Dr Reik said that there were two important subjects before the New Jersey Legislature.

1 Separate boards were proposed for the examinations of candidates for medical licensure—one board for regular practitioners of medicine, one for chiropractors, one for naturopaths, etc. This bill had little chance of passing.

2 An anti-rabic bill, sponsored by the State Department of Health, providing that dogs should either receive the anti-rabic inoculations, or be kept at home or on a leash.

Dr Reik distributed samples of literature on these two subjects prepared by the State Medical Society for popular information.

Fifteen clinics were scheduled every morning in the hospitals of the city, some of which were subdivided. The Medical School of the Western Reserve University did the unusual thing in arranging clinics by the departments of anatomy, physiology, histology, and biochemistry. Anatomy clinics were given on the practical subjects of the growth of children and the pathogenic tendencies of anatomic variability. The Department of Histology and Embryology demonstrated relation of the tubular embryonic heart to the cardiac patient. The Department of Physiology showed moving pictures of the mammalian heart and a simple

method for the registration of heart sounds, and demonstrated studies in respiration. In biochemistry there was shown the separation of hydrolytic products of proteins and the direct observation of the glomerular circulation in the frog. It is refreshing to find that the departments of medical study usually classed as pre-clinical were of direct interest to physicians engaged in the practice of bedside medicine.

Admission to the clinics was by cards which were given out only to the capacity of each clinic room. Some of the clinics were repeated.

The afternoon sessions consisted largely of symposiums. Among the subjects were diabetes, diseases of the heart and blood vessels, the gall bladder and liver, pediatrics, and the central nervous system. The subjects of the evening sessions were of a more general nature, and each program consisted of only two papers.

The names of the following physicians from New York State appeared on the program.

Dr Harlow Brooks, New York, Past President of the College, and a present member of the Regents of the College.

Dr W D Ayer of Syracuse, paper on pre-paralytic poliomyelitis, with results of serum therapy.

Dr Walter A Bastedo, New York City, paper on digitalis therapy.

Dr Frank B Cross, Brooklyn, paper on the recognition of carcinoma of the rectum and colon.

Dr Charles S Danzer, Brooklyn, paper on therapeutic procedures in pleural effusions.

Dr Allen A Jones, Buffalo, paper on coronary thrombosis.

Dr David Marine, New York City, paper on iodine in the treatment of goiter.

Dr P D McMasters, New York City, paper on urobilin, its physiology and pathology.

Dr C F Martin, Dean of the Medical School of McGill University, was elected president. New Orleans was named as the place for the next meeting, with Dr J H Musser, Jr, Professor of Medicine in Tulane University as chairman of the program committee. Tropical diseases will be the general topic of the meeting.

Any physician is welcome to attend the sessions. It is to be hoped that many physicians of New York State will attend the sessions in New Orleans and will find attendance at the meetings a happy way of combining business and pleasure.

## THE ANNUAL MEETING

Of course, you are thinking about attending the Annual Meeting of the State Society which will be held this year at Niagara Falls, May 9th, 10th, 11th and 12th. You have decided to go? That is splendid, we are sure you will have a delightful and profitable time.

You will add to the pleasure of your visit if you will make your hotel reservation early. For your convenience a list of hotels is again presented. These are regular prevailing rates and the same will be in effect during the meeting. The hotels on this list are members of the Hotel Association of Niagara Falls and can be depended upon as being just as represented.

Reservations should be made direct with the hotel. Should further information be desired please address Dr. George L. Miller, Chairman of the Committee on Hotels, Chamber of Commerce Building, Niagara Falls, New York.

The annual banquet will be held on Tuesday evening, May 10th. Following the banquet there will be given a ball in honor of President Fisher. You surely will want to come to the banquet and ball. If you wish to make up your own party or table, please do so, and advise Dr. W. Roger Scott, Chairman of the Banquet and Ball Committee, Niagara Falls, New York.

In a later number of the JOURNAL, which will be designated the Annual Meeting Number, the Committee on Arrangements will endeavor to give complete information upon all phases of the meeting.

FREDERICK J. SCHNELL, M.D.,

*Chairman, Committee on Arrangements*

## ROOM RATES

Names and Location	Person Capacity	Room One Person		Room Two Persons	
		with bath	without	with bath	without
Hotel Berris, 109 Falls St.	211	\$2 50	\$2 00	\$3 50	\$3 00

## ART EXHIBIT OF THE NEW YORK ACADEMY OF MEDICINE

The New York Academy of Medicine held an exhibition of works of art done by American physicians from March first to the fifteenth. The exhibit fills the large reception room on the ground floor and 545 articles are listed in the catalogue, done by 78 physicians. The predominating feature is the exhibit of pictures done in oil, water color, pastel, pencil and etching. The exhibit also contains photographs, sculptures, medals, woodcarving and inlay work.

The printed list of exhibits is arranged alphabetically according to authors, and runs from Dr. Robert Abbe to Dr. Max Wolf. A visitor gets the impression that some well-known physicians are as skillful in art as they are in medicine and surgery.

The catalogue contains the following introduction by Dr. Samuel W. Lambert, President of the New York Academy of Medicine:

"The activities of the members of the Medical Profession in literature and art form a side light on the lives of busy men which is very seldom brought to public view. It is more unusual to associate the profession with achievement in art than with success in literary or musical work. Many physicians have been skilled performers in music and some have become so famous in English literature that the lay public hardly knows that they were physicians at all. The careers, for example, of Oliver Wendell Holmes, Oliver Goldsmith, Tobias Smollett, were those of literary geniuses rather than of medical practitioners.

"The present exhibition is a first effort to put on public view the work of contemporary American physicians in the plastic and graphic arts. It is by no means an attempt to be complete, but an earnest effort to draw from the whole country has succeeded in bringing to-

gether examples from the far West as well as from the nearer cities of the East. It is an exhibition collected in New York and therefore a majority of the exhibits are from this city. It is hoped that subsequent exhibitions will follow and that a larger representation from the general profession can be gotten together. That busy doctors can find time to acquire the

skill to do the things shown in the Academy of Medicine at this exhibition, proves a most important fact that makes for health and contentment in life. Every man and woman should find a hobby to ease the routine of business and of home living. And this hobby should, at least, have an absorbing interest and preferably should demand a creative effort."

## BRONX COUNTY MEDICAL SOCIETY

A regular meeting of the Bronx County Medical Society, held at Concourse Plaza, on February 16, 1927, was called to order at 9 P. M., the President, Dr. Friedman, in the Chair.

The minutes of the last regular meeting of the Society were read and approved. The minutes of the last regular meeting of the Comitia Minora were read for the information of the Society.

The following were elected to membership: Morton Henry Aronsohn, Samuel Frant, Sidney H. Freilich, David Hertzberg, Lawrence Levy, John R. Lynch, Louis H. Merker, Clarence J. O'Connor, Adrian Paul O'Flaherty, Sam A. Scherl, Abraham L. Wincor.

Dr. Boas presented the Report of the Committee on Public Health and Medical Education. The Report dealt with the subjects of Health Education for the laity by means of lectures and newspaper articles, a general publicity campaign concerning Periodic Health Examinations with the cooperation of the Bronx Committee of the New York Tuberculosis and Health Association, running a Health Column in the *Bronx Home News* as formerly, diphtheria prevention and the necessity of giving toxin antitoxin to children.

The President emphasized the importance of this Report, especially in regard to circularizing patients in the matter of Periodic Health Examinations and having posters in doctors' offices suggesting toxin antitoxin treatment.

Dr. Lukin, for the Committee on Medical Economics, reported progress.

Owing to the unavoidable absence of Dr. Cunniffe, Chairman of the Committee on Legislation, Dr. Landsman reported for the Committee. There has been an investigation by a Joint Legislative Committee of the proposed licensing of chiropractors. Dr. Van Etten appointed men to appear before the Committee who well represented the rank and file of the profession and they showed that the medical men were not opposed to the chiropractors provided they fulfilled all the requirements which are required of the medical man and in addition submit to the retroactive clause, with which the chiropractors refuse to comply. A new Chiropractic Bill has been introduced in the State Legislature. The Chairman

of the Committee on Legislation states, as far as he knows, the general trend of the Legislature is against passing the Chiropractic Bill.

Dr. Gitlow submitted the Report of the Building Committee. The matter of meeting in the Professional Office Building is in abeyance because no building is going on there at present. Another place that could be purchased has been suggested. The Committee invites discussion by the members as to the possibility of purchasing a building. The President referred the Report to the Comitia Minora, which is to report back to the Society.

Dr. Weitzner, for the Social Committee, outlined the purpose of the Committee and its plans for the year. He announced that the Committee has arranged for a Beefsteak Dinner to be held on Monday evening, February 28th, at Ebling's Casino, and appealed to the members for their cooperation and attendance at this dinner.

Dr. Landsman introduced the following resolutions which were carried:

"WHEREAS, The Bronx County Medical Society having sustained a severe loss in the death of its honored associate, Philip Rifkin, M.D.

"Resolved, That the Bronx County Medical Society record the sense of its loss in the death of Dr. Rifkin and that a minute thereof be placed on the records of the Society, and be it

"Further Resolved, That a copy of these resolutions be transmitted to the family of our departed member."

The Scientific Program then proceeded as follows:

### PAPERS.

1 "Periodic Health Examination Service for High School Children," I. H. Goldberger.

2 "Backache from an Orthopedic Standpoint," Samuel W. Boorstein.

3 "The Diagnosis, Pathology and Treatment of Osteomyelitis," Frederic W. Bancroft.

Dr. Bancroft's Paper was discussed by Drs. Henry Roth, J. Lewis Amster, L. Miller Kahn and Samuel W. Boorstein.

I. J. LANDSMAN, M.D., Secretary.

# THE DAILY PRESS

## THE COUNTY HEALTH UNIT

The New York *Times* of February 26 makes an editorial comment on the Governor's hearing on county health units which is described on page 314 of this JOURNAL. Speaking of changed conditions brought about by increased eased and rapidity of travel, the *Times* discusses the county and state assessments for the elimination of grade crossings and the support of public schools, and continues

"The field in which there seems to be special need for enlarging the unit of administration is that of public health. The voluntary health agencies for the prevention of sickness and promotion of physical well-being in the rural areas and villages have gone on a county basis from sheer force of circumstances, Mr. Homer Folks of the State Charities Aid Association has stated. The only county that is now administering its public health activities as a county unit is Cattaraugus. It has had the financial assistance and special cooperation of one of the Foundations in this experiment, which has been extremely successful, but it is to be expected that voluntary agencies will cordially assist under authoritative leadership whenever

any county offers it. Moreover, state aid is available for every county which organizes its health work on a county basis. Under a law passed in 1923, the state reimburses the county for half of its health work.

"It is urged that every Board of Supervisors should, through a special committee, acquaint itself with the operation of the Cattaraugus County Board of Health, to the end that it may avail of the methods there employed. That county has been 'a proving ground' for health work, and visitors have come from nearly every part of the civilized world to study the plan.

"The Governor puts it succinctly when he says that we can't afford to lose what is spent for public health or education, for what is lost can never be made up. Whatever, is the best system of disease prevention and health promotion will be the most economical. Both economy and efficiency demand the county unit of organization and administration for both public and private health agencies."

The subject of county Health Departments was discussed editorially in the January 15 issue of this JOURNAL.

## THE PLAGUE OF HEALERS

The New York *Times* for February 24 announced the revocation of the medical license of Leonard Lincoln Landis, proprietor of "The House of Health," New York. The next day the *Times* commented editorially as follows:

"The State Board of Regents at Albany has taken away his medical license from a well-known proprietor of a 'House of Health' in this city. The complaints about his methods were varied, and certainly seem to justify the action of the Regents. But, though this was an important case, the Secretary of the Board of Medical Examiners seems to have been unduly sanguine in predicting that it would have the effect of largely cutting down 'quackery' in the medical profession. The very 'doctor' in question had snapped his fingers at the Regents in advance, and had said that it would not make a particle of difference to him if his license were taken away. He would go on making money out of the trusting public just as before.

"It is an undeniable fact that irregular practitioners have greatly increased in number in

this country, parallel with the efforts to improve medical education, to get rid of dubious schools of medicine conferring questionable degrees, and to stiffen the requirements for a medical license. In 1924 the Association of American Medical Colleges appointed a committee to make a special study of the whole question of medical education and medical practice in the United States. Last month it issued a preliminary report, in the course of which it stated that 'between 1910 and 1920 there was an increase of 116 per cent in the number of healers of various kinds other than medical practitioners and osteopaths. In all probability the numbers have continued to rise since 1920.' It is an old and curious story. Alongside science we always have ignorance raising its unabashed head. So long as a great multitude continues to have superstitious ideas about the causes and cure of disease, so long will healers flourish in the land, whether they are or are not permitted to call themselves doctors."

## THE POETRY OF SCIENCE

The poetry of science, so well illustrated by Fracastor's poem "Syphilis," reviewed on page 304 of this JOURNAL, is shown in these modern times by an address of Michael Pupin, Professor of elctro-mechanics in Columbia University. Speaking on electrons recently before the Alumni Association of the Polytechnic Institute of Brooklyn, Dr. Pupin is reported in the New York *Sun* of February 26 as saying

"The electron is the most law-abiding creature in the universe, the most ordinary intelligence can manage it. It loves, honors and obeys the law and its eternal mission is to serve

God employed the heavenly host of electronic workers to build the atoms, the molecules and the galaxies of burning stars. These celestial furnaces, throbbing with the blazing energy of the electronic host, are molding all kinds of planetary castings and tempering them so as to be just right for organic life.

"One of these primordial planetary castings is our mother earth, it is a mere dust speck in the universe, but this dust speck is the home of the soul of man, and this lifts our tiny earth to a place of honor near the throne of God. The soul of man is, as far as we know, the noblest product of God's creation. Its breath

of life is the beautiful electronic music, and to be thrilled by the melody of that cosmic song is the highest aim in our study of electrical science."

The poetry of science is further illustrated by the following poem on the new medical center of Columbia University, written by Dr. Elmer Ellsworth Brown, Chancellor of the New York University, and printed in the New York *Times* of March second

"Cliff on the cliff upraised by human hands,  
In morning mist, before the day is bright,  
Or in the mellow glow of evening light,  
Portentous, dominant as a dream, it stands,  
But when the Summer noon, in blocs and bands

Of sun and shadow, thrusts it on our sight,  
That naked form of majesty and might  
Speaks the stern veritas of desert lands

On such a crag was old Prometheus bound,  
But here the fire of Heaven shall rend the chain

And slay the vulture, here the sick shall find  
Life rounding out again its broken round,  
Nor all Olympus grudge the raptured gain,  
Where man shall grasp the power to heal  
mankind"

---

## WHEN IS A MAN DRUNK?

The need for tests for alcoholic intoxication was discussed editorially in this Journal on January first. The signs and symptoms of drunkenness have been investigated by a committee of the British Medical Association and its report is summarized on February 18 in the New York *Herald Tribune*.

The news item says that the report promises to be the toper's Magna Charta, for it discards such tests as thick pronunciation, wobbly gait, rapid pulse, and failure of convergence of the eyes, on the ground that all these signs may be produced by organic nervous diseases. The newspaper quotes from the report as follows:

"A person is under the influence of alcohol if there is a smell of liquor in the breath, provided there is a combination of all or most of all of the following groups of signs or symptoms

"1. A furred tongue

"2. Irregularities in behavior such as loquacity or sullenness

"3. A suffusion of the conjunctive and a reaction of the pupils

"4. Loss or confusion of memory, particularly as regards recent events and appreciation of time

"5. Hesitancy and thickness of speech and impaired articulation

"6. Tremors and errors of co-ordination and orientation

"Despite this list of tipping tests, the committee ends its report with a note of despair

"Drunkenness cannot yet be measured by any definite standard. The word 'drunk' should be taken to mean that the person concerned is so much under the influence of alcohol as to have lost control of his faculties to such an extent as to render him unable to execute safely the occupation in which he is engaged at a material time."

Although these tests may not be convincing, some judges are wise in their interpretation of signs and symptoms which they understand. The county judge of Nassau County in an address before the county medical society, said that an excellent test for drunkenness is to take off the hat of the suspected man and replace it on his head. If he does not try to refit it to his head, he is drunk. The theory is that no one can put on a hat for a normal man, or wipe his face to his satisfaction—he wants to do it over again.

## PLAGUES, CAMELS AND AUTOS

That the menace of the plague is increased by modern means of transportation is well brought out by the following editorial in the New York *Herald Tribune* of March third

"Half way between Manchouli, where the Trans-Siberian Railway crosses into Manchuria, and Urga, the capital of Mongolia, the pneumonic plague broke loose in November in the sudden mysterious manner in which it used to pounce upon Western countries. There had been isolated cases in the autumn among marmot-hunters—and the Mongolian marmot can play much the same role on the plains as the filthy rat plays in carrying the disease through the cities—but suddenly the disease struck down five hundred victims in two days. Those who escaped the malady fled and carried the germs with them, by mid-December half a dozen Mongol hamlets were infected. Immediately Russian doctors set out from Urga, Chinese doctors stood guard on the Manchurian frontier, and the plague was checked

"Caravans take at least a week to reach Man-

chouli from Sanpeitzu," Dr Wu Lien-teh, director of the North Manchurian Plague Prevention Service, reports, "so that individuals infected at the latter would be ill already when arriving in Chinese territory, and would, therefore, be detected. Motor cars take only a couple of days, but the passengers must be in good circumstances in order to afford such traveling. Consequently they are not likely to be in close quarters with the poor Chinese in their crowded winter quarters, where the disease may assume epidemic proportions

"The despised camel has its virtues, from the point of view of plague detection. When automobiles are cheap in North Asia the plague will spread more easily. But there on the dusty trade routes which are plied today as they were plied in Marco Polo's day and a thousand years before Marco Polo, the Black Death, which six centuries ago cut Europe's population in half, which until within a century was a constant peril to the West, whose germ was isolated only three decades ago, still stalks with the camels and takes its grisly toll."

---

## WHEN DANGER CALLS

*Collier's Weekly* for March 5 contains the following editorial entitled "When Danger Calls," which would be equally suitable for a Church publication or a Medical Journal

"A Negro school teacher of Manteo, N. C., cut her foot and developed tetanus

"The nearest doctor was miles away and so an ambulance seaplane from Hampton Roads was flown down to administer relief

"During a recent blizzard which filled the Iowa roads with snowdrifts four to six feet deep a five-year-old boy was taken critically ill

"An immediate operation was found necessary and the hospital was nine miles away

"News of that boy's peril aroused the town of Rowley and the entire community dug a road through twelve miles of snowdrifts

"Lives were saved because men were willing to work and undergo hardship without hope of reward

"The mere knowledge that an unknown Negro woman and a little child were in danger drove men out of their homes to fight for their safety

"Remember these things the next time the general cussedness of humanity seems quite intolerable

"An emergency nearly always brings out the good"

---

## DISABLED SOLDIERS

The New York *Times* of March 6th contains a brief summary of the conditions for which disabled French soldiers are receiving pensions. The article is as follows

"The tragedy of the World War was again brought home to Frenchmen today with the announcement of the official figures of the total number of French ex-service men receiving pensions on Jan. 1, 1927, because of permanent injuries sustained during the conflict

"Of the 700,000 listed, 404,606 are either leg-

less or armless or have but one arm or leg. 235,884 have consumption or lung troubles of various kinds, 27,281 have eye injuries, including 2,585 who are completely blind, 17,730 have ear deformations, including 4,338 who are totally deaf, 8,588 have disfigured faces and 14,502 are mentally deranged

"The total does not take into consideration many thousands of former soldiers whose permanent deformities do not entitle them to pensions because they have been classified as slight, that is to say, 10 per cent or less"

# BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review as dictated by their merits or in the interests of our readers.

**THE PRACTICE OF MEDICINE.** By A. A. STEVENS, A.M., M.D. 2nd Edition, entirely reset. Octavo of 1,174 pages. Philadelphia and London, W. B. Saunders Company, 1926. Cloth, \$7.50.

**STUDIES IN PSYCHOLOGY AND PSYCHIATRY** From the Catholic University of America. Edited by EDWARD A. PACE. Vol. I, No. 1. The Psychology of Reasoning. By MIRIAM FRANCES DUNN. Octavo of 141 pages. Vol. I, No. 2. Diastatic Activity of the Blood Serum in Mental Disorders. By JOHN WILLIAM RAUTH. Octavo of 32 pages. Baltimore, The Williams and Wilkins Company, June, 1926. Price per volume, \$5.00.

**THE TREATMENT OF CHRONIC DEAFNESS BY THE ELECTROPHONIC METHOD OF ZUNDBURGLET.** By GEORGE C. CATHCART, M.A., M.D. 12mo of 88 pages. London and New York, Oxford University Press, 1926. Cloth, \$1.35. (Oxford Medical Publications.)

**THE TREATMENT OF THE ACUTE ABDOMEN.** Operative and Post-Operative. By ZACHARY COPE, B.A., M.D. Octavo of 238 pages, illustrated. London and New York, Oxford University Press, 1926. Cloth, \$3.50. (Oxford Medical Publications.)

**SELF-CARE FOR THE DIABETIC.** For the Use of Diabetic Patients. By J. J. CONYBEARE, M.C., M.D. 12mo of 70 pages. London and New York, Oxford University Press, 1926. Cloth, \$1.15. (Oxford Medical Publications.)

**CHRONIC RHEUMATIC DISEASES.** Their Diagnosis and Treatment. By F. G. THOMSON, M.A., M.D. and R. G. GORDON, M.D. Octavo of 202 pages. London and New York, Oxford University Press, 1926. Cloth, \$2.75. (Oxford Medical Publications.)

**REPORTS OF THE ST. ANDREWS (JAMES MACKENZIE) INSTITUTE FOR CLINICAL RESEARCH,** ST. ANDREWS, FIFE. Volume 3. Edited by DAVID WATERSTON, M.D. Octavo of 227 pages, illustrated. London and New York, Oxford University Press, 1926. Cloth, \$3.00. (Oxford Medical Publications.)

**INFANT MORTALITY AND ITS CAUSES.** With an Appendix on the Trend of Maternal Mortality Rates in the United States. By ROBERT MORSE WOODBURY, Ph.D. Octavo of 204 pages. Baltimore, The Williams and Wilkins Company, 1926. Cloth, \$3.50.

**INTERNATIONAL CLINICS.** Thirty-sixth Series. 1926. Volume 4. Octavo of 308 pages, illustrated. Philadelphia and London, J. B. Lippincott Company, 1926.

**TRANSFUSION OF BLOOD.** By HENRY M. FEINBLATT, M.D. Octavo of 137 pages, illustrated. New York, The Macmillan Company, 1926. Cloth, \$3.00.

**CLINICS, HOSPITALS AND HEALTH CENTERS.** By MICHAEL M. DAVIS, Ph.D. Octavo of 546 pages. New York and London, Harper and Brothers, 1927. Cloth, \$5.00.

**HISTORY TAKING AND RECORDING.** By JAMES A. CORSCADEN, M.D. 12mo of 78 pages. New York, Paul B. Hoeber, Inc., 1926. Cloth, \$1.50.

**THE NORMAL CHILD AND HOW TO KEEP IT NORMAL IN**

**MIND AND MORALS.** Suggestions for Parents, Teachers and Physicians, With a Consideration of the Influence of Psychoanalysis. By B. SACHS, M.D. Octavo of 111 pages. New York, Paul B. Hoeber, Inc., 1926. Cloth, \$1.50.

**PRACTICAL SURGERY OF THE JOSEPH PRICE HOSPITAL.** By JAMES WILLIAM KENNEDY, M.D. Octavo of 861 pages, illustrated. Philadelphia, F. A. Davis Company, 1926. Cloth, \$10.00.

**SHELL SHOCK AND ITS AFTERMATH.** By NORMAN FENTON, Ph.D. With an Introduction by THOMAS W. SALMON, M.D. Octavo of 173 pages. St. Louis, The C. V. Mosby Company, 1926. Cloth, \$3.00.

**AN INTRODUCTION TO THE PRACTICE OF PREVENTIVE MEDICINE.** By J. G. FITZGERALD, M.D. Assisted by PETER GILLESPIE, M.Sc., C.E., and H. M. LANCASTER, B.A.Sc. 2nd Edition. Octavo of 792 pages, illustrated. St. Louis, The C. V. Mosby Company, 1926. Cloth, \$7.50.

**PHYSIOLOGY AND BIOCHEMISTRY IN MODERN MEDICINE.** By J. J. R. MACLEOD, M.D. LL.D. Assisted by ROY G. PEARCE, A.C. REDFIELD, N. B. TAYLOR, and J. M. D. ONLSTED and by others. 5th Edition. Octavo of 1054 pages, with 291 illustrations, including 9 colored plates. St. Louis, The C. V. Mosby Company, 1926. Cloth, \$11.00.

**DISEASES OF WOMEN.** By HARRY STURGEON CROSSEN, M.D. 6th Edition, revised and enlarged. Quarto of 1005 pages, with 934 illustrations, including one colored plate. St. Louis, The C. V. Mosby Company, 1926. Cloth, \$11.00.

**LOCAL IMMUNIZATION.** Specific Dressings. By Professor A. BESREDKA. Edited and translated by Dr. HARRY PLOTZ. Octavo of 181 pages. Baltimore, The Williams and Wilkins Company, 1927. Cloth, \$3.50.

**ACTIONS AND USES OF THE SALICYLATES AND CINCHOPHEN IN MEDICINE.** By P. J. HANZLIK, M.D. Octavo of 200 pages. Baltimore, The Williams and Wilkins Company, 1927. Cloth, \$3.50. (Medicine Monographs, Vol. IX.)

**THE SIGNIFICANCE OF THE PHYSICAL CONSTITUTION IN MENTAL DISEASE.** By F. I. WERTHEIMER and FLORENCE E. HESKETH. Octavo of 76 pages, illustrated. Baltimore, The Williams and Wilkins Company, 1926. Cloth, \$2.50. (Medicine Monographs, Vol. X.)

**MIND AND ITS DISORDERS.** A Text-Book for Students and Practitioners of Medicine. By W. H. B. STODARD, M.D. 5th Edition. Octavo of 593 pages, illustrated. Philadelphia, P. Blakiston's Son and Company, 1926. Cloth, \$7.50.

**MUSCULAR CONTRACTION AND THE REFLEX CONTROL OF MOVEMENT.** By J. F. FULTON, B.Sc. Octavo of 644 pages, illustrated. Baltimore, The Williams and Wilkins Company, 1926. Cloth, \$10.00.

**DE LAMAR LECTURES 1925-1926** (Johns Hopkins University—School of Hygiene and Public Health). By DAVID MARINE and others. Octavo of 220 pages, illustrated. Baltimore, The Williams and Wilkins Company, 1927. Cloth, \$5.00.

# OUR NEIGHBORS

## MEASURING COMMUNITY HEALTH

A department of health deals with the health of a community as a group of persons. The standards of measuring community health are discussed in the following abstracts from an article by Dr. James Wallace of the Iowa State Department of Health in the February issue of the *Journal of the Iowa State Medical Society*—  
EDITOR'S NOTE

"A writer who occasionally amuses himself by writing on medical subjects, says that ordinary standards are often inadequate as measures of health. He says, for example, that we should judge of a person's age, not by the number of years that have passed over his head, but by the number of colds that have passed through his head.

"1 One method of measuring community health is by sickness surveys, a very good yardstick, but impossible on a large scale and confined very largely to voluntary agencies that have plenty of liberty in determining how money donated for health work may be spent, or to aspirants for college degrees that can be obtained by making surveys of this nature. We have no knowledge of any of these being made in Iowa during the present year, except in one or two circumscribed areas, and anyway if made, they would be fragmentary and partial so far as the state is concerned.

"2 Occasionally we can get a general idea of the incidence of certain of the more acute diseases by a survey of hospital records, but there are still so many of these cases, as well as of the less serious ones, treated at home that no adequate conception of health or illness can be obtained except for a very limited area.

"3 The next yardstick within our reach is that of morbidity reports, the reports of cases of disease. In Iowa as in many other states, the reporting of cases of disease, with the exception of a few diseases, has been notoriously incomplete. That we have started on a new era of improvement is evidenced by a comparison of the number of cases reported in the first nine months of 1926, as compared with a corresponding period in previous years. Formerly, it was a common occurrence to find that for some diseases, a greater number of deaths than of cases were reported for the disease. For example, in 1924 for the first nine months there was not one case of tuberculosis reported, and only five for the whole year. In 1925 there were seventeen cases reported in the first three-quarters of the year, whereas for the year 1926

—January to September—there are 458 cases reported. The improvement in reporting of some other diseases is equally as striking, but all this indicates that up to the present time, the morbidity reports in Iowa would be a very unreliable index by which to judge the health of the state. But thanks to the cooperation of the health officers and physicians, if a proportionate improvement continues, by the year 1927 our morbidity figures will be fairly accurate indices of the state's freedom from or infection by disease. We have always to bear in mind that it is only the notifiable diseases that are reported, so that the great numbers that die from heart disease, cancer and other diseases are never reported as cases.

"4 The yardstick we have as yet to wholly rely upon for Iowa is the mortality reports, as the Census Bureau check on Iowa figures showed the death reports to be 92 per cent or over correct. We can make a fairly accurate estimate of the number of cases of any disease if we know the exact number of deaths, as while diseases vary in their virulence from year to year, there is a fairly definite and constant relationship between the number of deaths and the number of cases. We can be pretty certain that of typhoid fever cases, one in every ten to fifteen is likely to die, for diphtheria and tuberculosis, the ratio is about the same, for scarlet fever, one in every fifty, whooping cough, one in twenty-five, measles, one in one hundred, pneumonia, one in five, and for meningococcus meningitis, one in three. Smallpox varies so much in its virulence that it is difficult to name a ratio, but it varies from one in five to one in five hundred.

"The great majority of the population in Iowa are engaged in what is regarded as a non-hazardous and a healthy occupation, tilling the soil and the business of trade. Iowa enjoys high standards of and a wide diffusion of education which should give a background for, if not an actual cultivation of habits of health. Iowa too has a high standard of wealth, the per capita wealth being higher than almost any other state in the Union. This means that the people of Iowa are in a position to protect their health and to promote it. Public health is within certain limitations, purchasable, and as an editorial in the *A M A Journal* of October 9, 1926, shows in the case of Knoxville, Tennessee, it can be purchased and it pays to do so.

# The Management of an Infant's Diet

## Mellin's Food—A Milk Modifier

### Constipation

It is common observance among physicians who use Mellin's Food as a modifier of milk for infant feeding that their baby patients are seldom troubled with constipation, and if this annoying symptom does occasionally appear it is easily corrected by increasing the amount of Mellin's Food in the daily mixture or by some other slight readjustment of the formula

Some fault in the arrangement of the food formula is practically always the cause of constipation, so it seems logical to overcome the difficulty by rearranging the food elements to a more perfect balance rather than to employ medical means, which at best afford temporary relief only

In a pamphlet entitled, "Constipation in Infancy", the common causes of constipation are set forth for the physician's consideration, also practical suggestions for their correction. All of the matter presented is based upon observation extending over a long period and will prove of good service to every physician interested in the subject.

A copy of the pamphlet will be sent promptly upon request. Samples of Mellin's Food also if desired.

Mellin's Food Co., 177 State Street Boston, Mass.

A place where your patients can find attractive surroundings with adequate medical service and supervision.

Logan Clendenen in his recent classic 'Modern Methods of Treatment,' says 'The benefits to be derived from a Cure at a Mineral Springs depend, almost entirely upon the efficiency of the medical organization thereat. This principle has always been and still is the one which has so largely contributed to the deserved fame of the French Lick Springs Hotel at French Lick, Ind. When your patients are tired of home or hospital send them to us for final recuperation Through Pullman Service, New York to French Lick via Pennsylvania R. R.'

(Continued from page 326)

Iowa's climate which is not subject to great variations and its other natural conditions are far from being unfavorable to the health of its citizens. The state has an ample food supply, that is varied enough to contain all necessary vitamins, in fact to judge by the current "surplus" wail, one would suppose that the main ailment of the state is a form of indigestion due to a too liberal supply of a certain kind of food. Let us hope that the querulous laments reported in the papers do not indicate the general outlook of the people of Iowa, for one of the important factors in preserving and promoting health is a cheerful, hopeful, fearless outlook upon the future.

"Iowa with its many natural and acquired aids for health protection has, as we see it, two or three hindrances that result in preventing this state from surpassing practically all other states in matters of health. These are the natural water supplies and the drainage of the state. The natural waterways are lined by habitations, the watersheds we possess are thickly populated and the natural fall for drainage purposes is into the source of water supplies, so that we are continually exposed to water pollution. Moreover, the lack of ready drainage of the soil means that there is always a menace from flood borne disease. The experience of this last summer is sufficient proof of this. To completely protect our water supplies will no doubt make necessary many large and small engineering projects, while the disposal of human wastes in a rural state like Iowa will probably only be satisfactorily provided for when there is a full time health officer in each county thoroughly familiar with the best types of sanitary privies or disposal systems, who can show the people how easy it is to have a satisfactory system and at how little cost it can be installed. North Carolina has within the last five years made wonderful progress in the installation of such systems, but this would have been impossible without the adoption for their counties of a full time health organization.

"This leads me to say a word about the third break in the wall of our health defense in Iowa. This, I consider, is the lack in practically every one of our counties of an ever-acting responsible organization that gets into action not merely when there is an outbreak of a disease, but is working continuously to prevent both epidemics and sporadic cases of disease. Such an organization will give attention to all forms of disease. It will not be that tuberculosis alone or heart disease or any other individual or group of diseases will be campaigned against, but all the local and general factors that increase our morbidity and mortality rates undermine our happiness and increase our

(Continued on page 329—Adv. xv)

(Continued from page 328)

economic burden will be attacked, and if not completely eradicated, the number of sufferers will be reduced and the happiness and health of all conserved

"There is the incalculable element in health advancement as evidenced by the 'flu' epidemics, but in general we can make forecasts of the incidence of disease more accurate than the federal forecasts for the weather. So that in a county, if we have the machinery for health protection, we can work to avert or minimize the waves of disease that we are certain will reach our shores. Let us, therefore, provide the machinery."

### KINDNESS TO DOCTORS

The *Nebraska State Medical Journal* for March contains the following story which New York physicians may add to their armamentarium—THE EDITOR

One winter night, when the ground was covered with sleet, and the rain was freezing as it fell, the old doctor received a very late call from a family living way on the other side of the city. It was after one o'clock when he left home, and his horse—this was in the old days—slid all the way to the patient's house.

He got there about three o'clock, and found that a girl in the household had a severe cold. It was nothing dangerous.

"How long has she had it?" asked the doctor.

"Three days," answered the mother.

"Why didn't you call me in the daytime?" asked the doctor.

Then came the answer, which made this the favorite story of the Medical Society for many, many years.

"We are poor people, and we aren't able to pay very much, so we thought we would call you when you weren't busy."

### RESPONSIBILITY FOR PUBLIC HEALTH

The question is often discussed as to who is responsible for the practice of public health as distinguished from private practice. The question is well answered in the February 12th issue of the *Weekly Health Review* of the Department of Health of the City of Detroit. The article follows—EDITOR'S NOTE

Health Departments or some other properly constituted agencies must be responsible for the safety and purity of water and food supplies and the safe disposal of such wastes as might endanger the public health. They are likewise entrusted with the institution of such other measures as will tend to prevent the occurrence or spread of communicable disease,

including quarantine, isolation, and immunization There is some question as to how far they should go in the actual administration of immunization but there seems no doubt but that in the face of a threatened epidemic they are justified in offering public immunization These are all things over which the individual has little or no control except immunization

Does public responsibility cease with the control of these things over which the individual has no control? Officially, we believe, the responsibility ends here, except for the provision of medical and material relief for the indigent, yet the field of public health is far broader than this The control of these things will tend to maintain the public health at its present level and prevent further deterioration, but will not to any appreciable extent improve its present status Public health endeavor of today includes not only the prevention of disease, but also the building up of positive robust health To bring about any progressive and permanent improvement in public health there must be a course for school children in the fundamental principles of good health, and more universal acceptance and practice of prenatal care, regular medical attention for well babies, the development of proper mental attitudes among babies and pre-school children, regular dental care, periodic physical examinations for young and old, and the principles of personal hygiene, including regular hours, for sleeping and eating, a well balanced diet, and exercise in the direct sunlight

With the exception of the course in health for school children, which obviously must be supplied by the community, these things may be procured by the individual from his private physician and dentist The private physician and dentist are doing prophylactic work and are in a position to do a lot more of it The difficulty has been and is that the people as a whole are not sufficiently well acquainted with the very real benefits to be derived from scientific advice on these subjects to avail themselves, except in isolated instances, of this type of service This Department, therefore, hopes to create a more universal demand for scientific advice as to how to keep well and healthy Eventually it is to be hoped that the private physician will become the health officer for his clientele, not only preventing disease, but building up positive robust health through scientific advice as to habits of living

## THE WOMAN'S AUXILIARY

The Journal of the South Carolina Medical Association for January contains an account of the recent meeting of the Woman's Auxiliary of the Southern Medical Association in Atlanta—EDITORIAL NOTE.

"The opening session of 3,000 doctors assembled in the Auditorium Armory was interesting. A plentiful sprinkling of doctors' wives was apparent in the vast audience.

"The first business session of the Auxiliary members in the Academy of Medicine, 32 Howard St., was well attended. Your President and Delegate, Mrs. Carl B. Epps, were invited to be present at the Georgia Executive Board meeting. We heard splendid accounts of health work being done in our sister State. The wife of Gov. Walker, (a physician) who had lost a child with diphtheria, was instrumental in having a law passed whereby groups of children, as many as 200 in the same communities, were inoculated with toxin-antitoxin. Milk inspection, water analysis, hygiene distribution and many activities were reported by the various committees.

"The business meetings were filled with interesting reports from all the Southern states. Texas especially is forging ahead and setting an example worthy to be followed by the states where the work is new. One was much impressed by the zeal and interest displayed by the Auxiliary members and the intelligence they brought to bear on the problems confronting the medical profession. The American Medical Association has asked the Auxiliary to do one big piece of work, in placing the hygiene magazines in all schools, homes and libraries. Its purpose is to give authoritative advice on all matters pertaining to right living and healthful thinking.

"The social features of the convention were delightful. The 250 members of the Fulton County Auxiliary were ideal hostesses, planning everything for our com-

fort and pleasure. The Courtesy Committee called at the hotels and left flowers in the guests' rooms. The Transportation Committee had cars waiting to convey us to every social function. Tuesday, a luncheon given in the beautiful Atlanta Woman's Club was a feast of wit.

"The banquet at the Biltmore Hotel that evening was a brilliant affair. Fifteen hundred guests sat down to a sumptuous repast. Flower laden tables and gorgeously gowned women created a scene of fairy-like beauty. Mrs. Allen Bunce proved a capable and charming toast mistress. A program of aesthetic dancing and music followed. The Georgia Tech quartette delighted their hearers with several selections and encores.

"Wednesday a musicale at the Piedmont Driving Club and tea afterward gave the guests an opportunity to become acquainted. Mrs. Charles E. Dowman, a South Carolina artist, gave a piano recital of Handel and Scarlatti numbers. Mrs. Shallenberger in native costume, sang a group of Spanish songs. An eminent cellist assisted.

"Wednesday evening we attended the auditorium exercises (had the pleasure of seeing our friend, Dr. Horsley of Richmond, installed as the new president of the Southern Medical Association) and the President's ball which followed. We met many South Carolinians in the vast crowd. There ended successfully the second annual meeting of the Woman's Auxiliary to the Southern Medical Association.

"South Carolina's report and especially the work accomplished toward the Sims Memorial was received with interest. Many requests for information concerning this great physician were answered. Printed pamphlets were distributed among the delegates setting forth his glorious achievement for womankind.

"We returned filled with inspiration to work for a more complete organization so that South Carolina may take her rightful place in this great movement.

## THE NURSING SCHOOL OF YALE UNIVERSITY

The February issue of the *Illinois Medical Journal* has an editorial on the Yale University School of Nursing from which the following excerpts are taken—**EDITOR'S NOTE**

"To Yale University, pioneer education in this country, must be given a fresh laurel. This university has a school to train nurses

"From this school it seems as if relief might be expected in the nursing system that has become so well nigh impossible for either practitioner or patient to handle. The over-trained nurse has long been a thorn in the side of self-respecting physicians, and the overpaid and underworked nurse is beyond the reach of the great bulk of citizens

"This school may be the wedge with which the present nursing problem may be brought to some sort of compatible balance with existing circumstances as to sick persons, incomes, duties and hire

"Only too often does a doctor meet with the need of a nurse to which the retort courteous from his patient, is like the housewife who, quoting from the *Boston Medical and Surgical Journal* remarked, 'But I can't have a nurse, doctor, I'm too sick to look after her'

"Only too true is the fact that in many instances the trained nurse has come to regard personal service for her patient as beneath her dignity and below her personal standing. High standards for nurse-students has had something to do with this. Not all responsibility can be laid there, nor can any one excuse the American spirit of progress and desire for a safe-guarded old age, for making of the nursing profession what is really a cut-throat job where the patient is concerned

"Rapidly the high cost of elaborate training is limiting trained nursing to wealthy private patients, in their homes, and to institutions for the sick and convalescent, in fact, the entire

New York City

trend of the overtrained nurse is institutional. If an executive position is possible, so much the better. The personal love of individual care of the sick seems to have gone out with a horse and buggy

"Leaders in the nursing profession should take heed before the 'goose that lays the golden eggs' meets an untimely death. Conditions are intolerable in the way of having some one take care of those who are ill at a price that the sick can pay, instead of at the present prohibitive rate in Illinois and many other states. The school at Yale University is vivid writing on the wall. What this institution has done, others are going to do. Being affiliated with an institution of the high standard of Yale University will leave the nurses trained there free from the criticism attaching to the 'mail-order nurse'

"And here is where public opinion and the bulk of the medical profession will stand to the last ditch by capable, willing, careful women who are not afraid to do what a plain nurse ought to do. Americans have a mania for organizing and often organization out-does itself. This would seem to be about what has happened with the nursing profession. Keeping up the standard is an excellent motto, both by current members of an organization or by fresh applicants. But when an article becomes beyond the reach of those whom it is destined to serve, then it is time to reconstruct. When the automobile was a rich man's toy—as figuratively speaking the trained nurse is today, when it cost upwards of \$100 weekly for an all time nurse—two women working at \$50 each—it was a machine to be regarded with awe and wonder and envy, but not purchase. Along came Henry Ford and put a serviceable automobile on the market at a price within the income of almost the entire American citizenry. The comparison is too obvious to need comment"

## "Better-Tasting Codliver Oil"

Nason's *Palatable* Codliver Oil has that fine inimitable flavor which makes it "easy to take"—a flavor that no other codliver oil possesses. This agreeable taste assures you that your patients will take Nason's Codliver Oil when you prescribe it and gain the full benefit of its rich vitamin content.

Nason's Codliver Oil is biologically tested and standardized. Each teaspoonful contains more than 2,000 units of vitamin A (over ten times the U S P X standard).

Mail the coupon today for a sample of this "better-tasting" Codliver Oil. It is put up in 4- and 12-ounce bottles especially for the physician's prescription.

## STRICTURE OF URETER ITS ETIOLOGY AND TREATMENT\*

By CYRIL KLOCK CHURCH, M.D., NEW YORK, N Y

From the James Buchanan Brady Foundation for Urology, New York Hospital

THE purpose of this paper is to present an analysis of 100 cases of stricture of the ureter, and to review the literature on this subject, and finally to bring the tremendous importance of this subject more forcibly before the medical profession

### LITERATURE

Hunner<sup>1</sup> of Baltimore first put this clinical entity clearly before the medical profession, and he is of the opinion that focal infection is the primary etiological factor Bottomley<sup>2</sup> and Eisendrath<sup>3</sup> have written extensively on the congenital origin of strictures Kelly<sup>4</sup> has stated that strictures are caused by inflammation in the ureteral wall, produced by the common cocci and the gonococcus and tuberculosis Garso<sup>5</sup> states that the chief cause of stricture is the gonococcus Furniss<sup>6</sup> also believes that stricture follows hæmatogenous infection, which produces inflammation in the ureteral wall Sugimura<sup>7</sup> thinks that the infection extends through the lymphatics, and not along the mucosa Necker<sup>8</sup> is of the opinion that infective hydronephrosis is secondary in origin Kelly and Burnam<sup>9</sup> express the view that traumatic stricture often follows the injuries of labor and surgical operations, especially the Wertheim operation Cuthbertson<sup>10</sup> states that injury to the ureter is certain in vaginal hysterectomy Morris<sup>11</sup> collected reports on 5 cases of gun shot and stab wound injuries of the ureter Hunner refers to the work of Proksch<sup>12</sup> when he mentions that lues ought to be kept in mind Carey and Laird<sup>13</sup> describe cysts in the ureter, and these might act as obstructions, if not actually being classed as strictures J M Baker<sup>14</sup> also strongly favors focal infection Thomas and Mellen, in a paper entitled, "Bilateral Cystocele of the lower end of the Ureter," come to the conclusion that focal infection is at times the causative factor James Israel<sup>15</sup> concluded that most cases of essential hæmaturia showed organic changes in the kidney or capsule or an undue mo-

bility Kretschmer<sup>16</sup> proved that kidney specimens from cases diagnosed as essential hæmaturia had definite nephritic or nephritic-like changes Strauss<sup>17</sup>, coworker of Israel, believes that gross bleeding takes place when the intrarenal pressure is greatly increased, which occurs when the kidney capsule is very rigid, or when there is compression on the renal pedicle Hunner demonstrated stricture in 18 cases of essential hæmaturia Jehle<sup>18</sup>, Meyer<sup>19</sup>, and Nassau<sup>20</sup> are agreed that orthostatic albuminuria is due to lumbar lordosis, producing compression of the inferior Vena Cava and consequently renal stasis Sonne<sup>21</sup> catheterized 11 such cases, and in all only the left side was involved F C Rosenow and J G Neisser<sup>22</sup> seem to have established the causal relationship between kidney stones and streptococci Braasch<sup>23</sup> believed that the dilatation of the renal pelvis, in cases which had considerable infection, was not due to obstruction in the ureter, but was due to changes in the tissues and consequent retraction of their walls O S Fowler<sup>24</sup> mentions the possible importance of stasis in the etiology of stone.

The symptoms of stricture according to Hunner are

- 1 Pain the most universal symptom, and any place from the diaphragm to the ankles
- 2 Bladder symptoms occurred in 71 per cent of cases
- 3 The urine may be quite negative.
- 4 Fever occurs whenever the stricture closes and even if there is no infection
- 5 Gastro intestinal symptoms are common, and vary from slight aversion to food to extreme vomiting, gaseous distension, rectal tenesmus, pain just before or during stool, and even severe mucous colitis
- 6 The milder degrees of the uremic state, *e g*, headache.

J M Bartrina<sup>25</sup> states that disturbances in the urethra and prostate are common with stone in the kidney or ureter, also intestinal disturbances

\* Read at the Annual Meeting of the Medical Society of the State of New York, at New York March 31, 1926

from simple constipation to pseudo-occlusion and spasmodic pains. He also observes that the injection of an anodyne per rectum will better relieve a kidney colic than its administration by any other method. Osley Grant<sup>26</sup> states that the more typical is the classical clinical picture of stone the less certain it is that the condition is stone, and the more probable it is that it is stricture. D W Tovey<sup>27</sup> believes that palpation of the ureters should be part of every vaginal examination, and says that Pawawolick in 1880 catheterized the ureters by using the ureteral ridges on the anterior vaginal wall as guides. Branford Lewis<sup>28</sup> draws attention to what he calls a new sign in the diagnosis of ureteral stone: a metal dilator is inserted into the ureter and the stability of the former is sufficient to push the latter from its normal position, and so a shadow, which is in the ureter will move with it, and one which is not will not. This makes it easy to detect a phlebolith. C J Crowell and Raymond Thompson<sup>29</sup> give a good technique for the removal of ureteral stone without operation. Coffey's<sup>30</sup> work on dogs and Charles Mayo's work on man, would seem to indicate that there is a field for colon implantation of the ureter in cases where the stricture is near the bladder, and of such a nature that open operation is required. F W Braasch in August, 1920, wrote concerning the contraindication for operation for stone in the ureter and kidney, and makes the general observation, amid much good and important detail, that 75 per cent of stones will pass spontaneously, and that unless pain is excessive one should wait at least 6 months before operating. Judd<sup>31</sup> states that an inflammation producing a true stricture requiring operation is not common. W H Battle<sup>32</sup> gives a good technique for the removal of stone from the pelvic portion of the ureter by a method which combines the intra and extra peritoneal approach. O S Lowsley<sup>33</sup> gives a good technique for the removal of stone from the lower portion of the ureter and in the male only and by the perineal route. R L Latchem<sup>34</sup> makes it quite plain that complete obstruction in the ureter does produce disastrous results, and on this subject he quotes Caulk, as having shown that if the ureter is tied off by a plain cat gut, then the cat gut is absorbed in three weeks, and the lumen reopens in from six to eight weeks, but that in the meantime the kidney, unless it has been nephrostomized, would be past the point of function, and he states that Johnson before the work of Caulk had shown that if the obstruction in the ureter does not last more than two weeks function might possibly return. F T Lau<sup>35</sup> in writing on recurrent calculi advises that the chemical composition of stones be studied with a view to arresting faulty metabolism, and correcting if necessary the urinary reaction, but he also advises the removal of focal infection.

## EMBRYOLOGY

That ureteral stricture is a very probable cause of diverticulum of the ureter, is well brought out by Hale and Geldhern<sup>36</sup>, who reviewed the literature on the subject of diverticulum and who have done very considerable work on the subject. That, however, it is not the only cause of diverticulum is supported by the embryology of the formation of the ureter, and thus these authors admit. On the embryology of the ureter, and its possible relationship to the formation of ureteral diverticula, these authors state that the anlage of the ureter and kidney appears in the fourth week, as a hollow evagination, from the dorsal aspect of the mesonephric or Wolffian duct, near its junction with the cloaca. This evagination dilates at its extremity and proceeds to grow, first dorsad and thence cephalad along the vertebral column. The stock becomes the ureter, the proximate portion of the primitive ureter opens into the mesonephric duct at an acute angle, but when the cloaca becomes the urogenital sinus and rectum, then the mesonephric duct and ureter assume independent openings, with the ureter at a higher level. It is evident that if at the time of the development of the ureter, a secondary budding should occur, it would undoubtedly be absorbed by the bladder and either disappear or assume a separate opening into the bladder. May the present writer here note that should the latter occur, that is, should the secondary budding assume a separate opening into the bladder, here is the origin of a double ureter. Hale and Geldhern go on to say, that if, however, the secondary budding occurred after the formation of the ureter and kidney pelvis and after these structures had assumed their approximate anatomical positions, such a budding might in later life assume the appearance of a diverticulum—it could be likened to an abortive attempt at the formation of a second ureter. They say, however, that this is unlikely in the case they present, as there was found a stenosis of the ureter just below the opening of the diverticulum, and they argue that the presence of two distinct abnormalities in such close relation must necessarily be more than mere coincidence, and that one is justified in concluding that the one is the cause of the other.

## METHOD USED IN MAKING A DIAGNOSIS

1 History This was always very carefully made and more carefully considered, as it very obviously should be, and especially in cases with obscure abdominal pain.

2 Physical examination This should include careful palpation of the kidneys bimanually and of the ureters, which latter structures should also be investigated very carefully per rectum and vagina.

3 Cystoscopy The detection of points of nar-

rowing by means of ureteral bougies and catheters

4 **Pyelography** This latter method we have found very satisfactory for demonstrating stricture of the ureter

5 **The relief of symptoms** By treatment of the conditions, and this relief being obtained when all other means had failed to give relief

6 **The reproduction artificially by means of bougies, catheters, or by pyelography of pains similar to those of which the patient originally complains**

In discussing pyelography, let me say in answer to those who maintain that many of the constrictions seen in the pyelogram are merely due to spasm of the smooth muscle of the ureter, which we all know may occur at any time, and especially under stimulation, that this theory of the production of the constricted area cannot be held when such constrictions appear in 4 or 5 consecutive pictures, as any spasm surely would not be maintained at exactly the same place for any length of time. Wax tipped catheters were not often used in this series as pyelography was depended upon

#### DISCUSSION OF CASES PRESENTED

The following is an analysis of 100 cases studied in this series. As to appearance it may be stated that 2% occurred in the second decade of life, 23% in the third, 33% in the fourth, 22% in the fifth, 13% in the sixth, 4% in the seventh, and 3% unstated. The youngest age in which the condition occurred was 14 years, and the oldest 71 years. The average age was  $37\frac{1}{4}$  years.

No definite statement could be made as to whether or not occupation influences, the incidence of ureteral stricture, inasmuch as it was only stated in 12% of the cases, but it is to be noted that the recorded 12% all had sedentary occupations.

Males in this series represented 65% of the cases and females 35%, so that it may be said that the condition is at least as common in males as it is in females.

With regard to race it may be said that 18% were of North European extraction, while 15% came from countries surrounding the Mediterranean Sea, 67% were born in the U S A.

Fifty per cent of the cases were married.

There were 93 cases admitted to hospital. The duration of the longest case was 129 days, but this included 6 different admissions. The shortest stay in hospital was 1 day. This represented 23 of the cases. And so the average stay in the hospital was 10 days, and this only if one includes 2 very long cases. If these latter are excluded, the average stay in hospital was 7 days.

The family history was negative in 84% of cases, and positive in 16% of cases. Six of these latter had had kidney trouble.

Fig 1—Case showing kink and stricture, and moderate hydronephrosis

The past personal history was negative in 42% and positive in 58% of the cases. Thirty-one cases had had previous operations. Twenty-six cases had had previous fevers. Seven cases gave previous history of pain being the only symptom. Two cases had pyorrhea. One case had suffered from blurred vision. One case had had a left hemiplegia. Six of the cases gave a history of having had previous subjective troubles, *e g*, vertigo. Two cases had suffered from eructations of gas. Fifteen of the cases had had previous gonorrhea, and two of the cases gave a history of leues. Two cases had passed stones per urethram and two had had haematuria, and there were two cases of frequency.

Of the 31 cases, which had previous operations, four were for pyelotomy, and two for nephrectomy. Of the two latter it may be said that had there been proper diagnosis sufficiently in advance at least two kidneys would have been saved. There was one case, which had had a herniaectomy, and thus of course warrants no comments. There were seven cases, which had had pelvic operations, the exact nature of which it was impossible to ascertain, but it is to be presumed that they were undertaken and in fact in some of the cases this is surely certain, to relieve symptoms, which were really due to uterteral stricture. The patients did not get relief in these cases, and so it is fair to assume that they represented er-

rors in diagnosis, as is also more than probably a fact in 10 other cases, which had had their appendices out. Two cases had a fistula in ano. And one case had had rectal abscess. One case had had a tonsillectomy, and these tonsils were no doubt removed because they were infected. One case had had a cholecystectomy, which latter case it is not impossible to suppose may also represent an error in diagnosis. There were two cases which had had operations for bladder tumor. There was one patient who had had a goitre operation, which was performed to rid the patient of nervousness, which it is more than fair to presume, in the light of the later history of the case, may have at least been accounted for in part by poor kidney function. There were two surgical conditions diagnosed but not operated upon, viz., one case of right inguinal hernia and one case of appendicitis.

Of the 26 cases which had had previous fevers, there were two cases of malaria, five cases of tonsillitis, four cases of influenza, one case of cholera, two cases of typhoid, one case of dysentery, two cases of diphtheria, four cases of scarlet fever, two cases of measles, two cases of mumps and finally one case, which was described as having had a "bad cold." It will of course occur to anyone that all of these cases just quoted are potential sources of focal infection.

The present illness. The character of the onset in 37% was sudden in nature, and gradual in 63% of cases. Pain was the most universal symptom, having occurred in 90% of cases, in 10% of cases there was no pain. Considering the duration of the pain in those cases in which it existed, it may be said that in 10 cases it lasted from one to ten days, in 10 cases from two to six weeks, in 23 cases from one to ten months, and finally in 47 cases from one to thirty years. In considering the location and character of the pain, it may be observed that in 64 cases it was in the lumbar region, and that of these 26 cases had sharp pain and 38 dull aching pain. Fourteen of the cases had abdominal pain, eight of these having had sharp pain and six dull pain. One case experienced pain above the crest of the ilium, four cases had pains in the groins. Of these two being sharp and two dull pains, eight cases had pains along the course of the ureters. Four of these having had sharp pain and in four the pain was dull. Lastly two cases complained of supra pubic pain. Here it may be remarked that in Hunner's cases pain too was the most common symptom, but that in most of his cases it occurred chiefly in the broad ligament area, which of course corresponds roughly to the lower portion of the ureter.

Seventy-one per cent of Hunner's cases presented bladder symptoms, and this figure is taken from his paper on "The Essential Hæmaturias." Sixty per cent of the cases in this series presented bladder symptoms, and the details are as fol-

lows. There was frequency in 47 cases, nocturia in 29, dysuria in 35. Haematuria in 20, stranguary in 4, and incontinence in 1. In 6 cases haematuria was the chief symptom. In one case it was the only symptom, and in another case it was the only symptom, but in this latter was very severe. In one case the haematuria was terminal. In one case it was very slight. In one case it was very slight and only occurred once. In one case the hæmaturia had a duration of three years, and in one case the bleeding was mostly at night. In one case dysuria was the chief symptom, and in 9 cases frequency was the chief symptom. From the above it is fairly apparent that these symptoms referable to the bladder are fairly constant and may be severe, also of course

Fig 2—Case showing stricture of the ureter and large hydronephrosis

there may be all kinds of combinations of these various urinary symptoms.

Five cases presented symptoms referable to the nervous system, four of these were very nervous and one of them slept very badly.

Gastro intestinal symptoms were present in 21 cases, thirteen having had nausea, two vomiting, two eructations of gas, two anorexia, and two flatulence.

Three cases had lost weight, three cases were having chills, and one case had passed a stone, these latter of course coming under the heading of miscellaneous symptoms.

*Physical examination* Eighty-eight per cent of the cases appeared to be in good health, 4% appeared to be in fair health only, and 7% certainly seemed to be in very poor health. One case had disturbance of endocrines.

*Temperature variations* There were 27 cases in which the temperature ranged about 98 degrees Fahrenheit, 26 cases ranged about 99 degrees F, 16 cases ranged about 100 degrees F, 6 cases about 101 degrees F, 7 cases about 102 degrees F, 8 cases about 103 degrees F, 8 cases 104 degrees F, 2 cases 105 degrees F. One of the 7 cases with a temperature of 102 occurred post operatively, and also one of the cases with a temperature of 103. One of the cases with a temperature of 103 occurred after pyelogram. Of the cases which had a temperature of 104, one occurred after pyelogram, one post operatively, and two had chills, and one had chills for four days, two of the cases with a temperature of 105 also had chills.

An examination of the head and neck showed positive findings in 35% of cases. One case showed great pallor. One case had the sense of hearing diminished by about 25%, and in one case it was diminished in the right ear by the same per cent. In one case the posterior nodes were palpable, in one case the thyroid was bilaterally enlarged, in 16 cases the teeth were in fair condition and in 6 cases they were in very bad condition, in three cases there were extensive pyorrhoea, and in three cases all the teeth had been extracted, also there were two chronic cases of follicular tonsilitis. It will be seen that any one of the last 30 cases mentioned are very probable sources of focal infection.

Three cases had the soft systolic murmur at the apex of the heart, but the murmur was not transmitted to the axilla. There was one case of soft systolic murmur at the apex which was transmitted to the axilla. In all these the lungs had negative findings. There was one case in which there was a moderate babinski, and one case in which the knee jerk was absent, and another in which this latter reflex was hard to elicit.

An examination of the abdomen showed that in two cases the kidneys were palpable on the left side, and in four cases palpable on the right side, and one case palpable on the right and left side. There were four cases in which the kidney seemed to be tender by palpation anteriorly on the left side and five cases in which they were tender on the right side, and one case in which tenderness was demonstrated on the right and left side, in no case the kidney was both palpable and tender on the left side, and there was only one case in which it was both palpable and tender on the right side, and also there was only one case in which they were both palpable on both right and left side. Of the kidneys which were palpable on the right side one was very

low and one was very large. So it will be seen that in all there were 19 cases in which the kidney or kidneys were either palpable or tender or both. There were 11 cases in which tenderness was demonstrable in the right costo-vertebral angle, and 5 cases in which the same could be demonstrated for the left side, and there was one case in which there was costo-vertebral tenderness on the right and left side, in all 17 cases. There were 5 cases in which there was tenderness in the suprapubic region and there were two cases in which tenderness could be elicited along the course of the ureters, a total of 7 cases. If these totals are added it will be seen that in 43 cases a kidney condition was demonstrable by means of simple physical examination. The recti

Fig 3—Very definite case of stricture in the series

muscles were rigid in two cases on the left side, and in the upper part of the abdomen. In two cases they were tender. In no case were they rigid and tender on the upper left side. On the right side the upper right rectus was rigid, in four cases it was tender, and in two cases it was both rigid and tender. Tenderness only could be demonstrated in the region of the lower rectus in 5 cases on the left side and in 2 cases on the right side. If we add these latter we have a total of 18, which figure added to the figure 43, which represents the kidney condition demonstrable by physical examination, gives a grand total of 61.

cases in which there were positive findings in the abdomen

The blood pressure records were all within normal limits

*Urnalysis* The reaction was acid in 80% of cases and alkaline in the remaining 20%. The specific gravity was 1000 and over 16%, 1010 and over in 35% and in the remaining 49% it was 1021 and over. There was a trace of albumin in 41% of cases and a considerable amount in 2% of cases, making a total of 43% which had albuminuria. In no case was there demonstrated sugar in the urine. Thirty per cent of cases had a moderate amount of pus, and 7% of cases had a considerable amount, making a total of 37%, which showed pyuria. Two per cent of cases showed a slight amount of blood in the urine and 25% a considerable amount, making a total of 27%, showing haematuria, 20 of these cases had gross haematuria. There was only one case in which casts were demonstrated.

*Rectal examination* In 65 males there were only 5 cases in which the prostate was abnormal, in one case it was twice normal in size, hard and fibrous, in one case it was twice normal in size and boggy, and there was a residual urine of 5 cc, in one case it was slightly enlarged, in one case it was boggy, and finally there was one case in which it was enlarged and the seminal vesicles were also enlarged.

*Cystoscopy* Twenty cases showed cystitis. There were 7 in which there was trabeculation, 9 cases showed prostatic intrusion, and there were two cases which had stone in the bladder. The ureter mouths showed positive findings in 21 cases on the right side. In 15 cases they were inflamed or congested. In 3 cases they were difficult to find. In one case a number 3 catheter only was admitted. In one case pus was seen coming from it, and in one case there was a small ureterocoele. The left ureter mouths showed positive findings in 17 cases. In 11 there was congestion. In three they were hard to find. In one only a number 3 catheter was admitted. In one a clot of blood was seen hanging from it, and finally in one case there was a large ureterocoele. In this series there were no strictures of the female urethra recorded.

*Catheterization of the Right Ureter* In 80 cases the catheter passed to the kidney pelvis on the right side. In 73 cases a number 6 catheter was passed. In 6 cases a number 5 only, and in one case only a number 3 F could be passed. In 2 cases obstruction was met 4 cm up and was not passed. In one case obstruction was met 5 cm up and could not be overcome by a number 5 F catheter. In one case obstruction was met 6 cm up and was not passed by a number 4 F catheter. In 4 cases obstruction was met 10 cm up and was not passed. In 4 cases there was an impassable obstruction 15 cm up and in another case the

same was encountered 22 cm up the ureter. In 3 cases the only recorded description is that they are strictured. One case is described as difficult to catheterize. In two cases there was obstruction very near the mouth and it was not passed. Finally there was one case in which the right kidney had been removed. In 78 cases a catheter was passed to the kidney pelvis on the left side. In 64 of these a number 6 F catheter passed and in 10 of these cases only a number 5 F could be made to enter the pelvis. In 2 cases only a number 3 was admitted to the kidney pelvis. In 2 cases obstruction was met 2 cm up and was not passed. In one case it was met 3 cm up and was not passed. In one case 5 cm up and not passed. In 2 cases 6 cm up and not passed, and

Fig 4—Case 94 in the series. Details appear in body of paper. Double pyelogram.

in one of these latter a number 4 F catheter was used. In 2 cases there was impassable obstruction 10 cm up and in one of these a number 3 F catheter was used. In 2 cases obstruction could not be overcome 15 cm up and in one of these a number 5 F catheter was employed. In four cases obstruction was not overcome after passing a catheter up 23 cm. In one case there was an impassable obstruction 25 cm up. In 2 cases it is simply recorded that the ureter is strictured. In 5 cases the left ureter was not catheterized.

The following is an example of a case in which there is a demonstrable difference in the phenol-

sulphone-phthalein test and in the grams urea per litre test, and adversely on the side which was the seat of chief complaint

In case 52 in which the chief complaint was that of right sided pain and in which subsequently a stricture on that same side was demonstrated, a number 6 F catheter passed to the kidney pelvis on both sides, and the appearance time of the phthalein test was three minutes on the right side and two minutes on the left side. That is it took one minute longer to appear on the affected side, 6 per cent of dye was secreted in 14 minutes from each side. The grams urea per litre was 10 for the right side and 12 for the left side, that is the left comparatively good side put out relatively more urea than the affected side.

I have records of 21 other cases in which the same deficiency of the affected side could be further detailed and in which subsequently stricture was proved to exist on the side mostly complained of, but let the above example suffice. In the remaining 78 cases of the series the difference is not sufficient to warrant any dogmatic deduction. In only 21 cases did it check up.

*Location of the Stricture in the Ureter* There were 11 cases of stricture of the upper ureter, 5 occurring on the right and 6 on the left. One of these cases on the right side had a very definite stricture in the lower third of the ureter as well, and another one at the meatus. One of these cases on the left side also had another one in the lower third 10 cm up. Another of these where the stricture was 3 cm below the pelvic junction, also had another stricture in the lower third 4 cm up.

There were 4 cases of stricture at the junction of the upper and middle, third, two on the right and two on the left side. In one case on the right side there was a second stricture in the lower third. In one of the cases on the left side, there was a second stricture at the brim of the pelvis.

There were 6 stricture in the middle third of the ureter, 4 on the right side and 1 on the left, then there was 1 case in which a definite stricture was proved at autopsy. One of the cases on the right side also had another stricture in the lower third at the level of the brim of the pelvis.

Stricture at the junction of the middle and lower thirds, there were 3 cases demonstrating a lesion at this point, and in one of them the stricture extended from the upper level of the fourth to the upper level of the fifth lumbar vertebra.

*Stricture in the Lower Third* There were 21 cases showing stricture in this location, 12 on the right and 9 on the left side. Six of these were at the brim of the pelvis, 4 on the right side, and 2 on the left, 1 on the right side was very definite and there was another at the meatus,

and also there was one in the upper third of this same ureter.

There was 1 case simply described as multiple strictures right and left, and also a second case likewise described. There were 3 cases described as having several strictures on the left side. There was 1 case which had both ureters strictured. There are 2 other cases, which can be described as generally constricted.

The above is an analysis of the strictures occurring in 42 cases in which these conditions were definitely demonstrated by pyelogram, except the 1 case which is demonstrated by autopsy.

There were large kidneys in 9 cases, 5 on the right, 1 on right and left side, and 3 on the left side. There was ptosis in 20 cases, 14 on the

Fig 5—One of the cases showing stone, kinks, and strictures and largo hydro-pyonephrosis

right side, 5 right and left side, and 1 on the left, 2 of these cases were very marked. There was hydronephrosis in 39 per cent of cases. It was slight in degree in 17 cases, 10 being on the right side and 8 on the left side. The extra case noted is due to the fact that hydronephrosis existed in one case on both right and left side. The hydronephrosis was moderate in 7 cases, 4 on the right side and 3 on the left. There was marked hydronephrosis in 12 cases, 6 on the right and 6 on the left. In 2 of these cases the pelvic content was from 18 to 24 cc on the right side. In 2 of

these cases the pelvic content was from 24 to 30 cc on the left side. In 3 cases there was slight fraying on the left side.

There were filling defects in 1 case both on the right and left side. Relaxed ureters existed in 9 cases, 7 on the right and 2 on the left side. There were 2 cases exhibiting the anomaly of double pelvis on the left side. There was 1 case in which the pyelogram was unsatisfactory. In this series 14 kinked ureters were found, all of which were in the upper half of the ureter, 9 on the right side and 5 on the left. There were 5 cases, which showed angulation and all on the right side. There were 22 cases showing a dilated ureter, 14 on the right side and 8 on the left. There were 6 cases diagnosed as stones, 5 of which really were stones, 2 on the right side and 3 on the left, the remaining one really turned out to be a tumor, which was seen at operation. One of these stone cases existed on the right and left side, and the stones were multiple, 2 years later there was no evidence of any stone. In another of these cases the stone was just inside the ureteral orifice and was the size of an olive pit. There were 10 cases that had no X-ray at all. There were 9 cases in which the X-ray findings were negative.

*The Microscopic Examination of Ureteral Specimens* In 81 cases they were negative. In 19 cases they were positive, and of these latter 10 showed pus, 9 blood and 3 casts.

*The Chief Complaint* In 84 cases the chief complaint was pain. In 9 cases it was frequency. In 1 case it was dysuria, and in 6 cases it was hæmaturia.

*Culture on Ureteral Specimens* There were 21 cases in which cultures were taken, of these 9 cases were negative on both sides, 4 cases were positive for *B. coli*, 1 case the *B. fluorescens* on the right side and negative on the left side, 1 case was negative on the right side and gave *B. fluorescens* for the left, 1 case gave *B. coli* and *staphylococcus albus* on both sides, 1 case was negative on the right side and *B. coli* on the left, 1 case *B. coli* on the right side, 2 cases negative on the right side and *B. pyocyaneus* on the left side. In Hunner's second group of fifty cases cultures were taken in all cases, and of these 16 per cent were infected with colon bacillus and 8 per cent were bilateral.

#### TEN CASES WHICH CAME TO OPERATION

Case 21 Right ureterotomy for stricture.  
Case 25 Nephropexy thickened ureter, no stone.  
Case 29 Right nephrectomy disorganized kidney.  
Case 31 Left ureterotomy and pyelotomy stone.  
Case 35 Left nephrectomy pyonephrosis.  
Case 37 Right nephrectomy tumor.  
Case 41 Left nephrectomy inflammatory.  
Case 58 Ureterotomy and obstruction overcome by passing bougie to bladder.

Case 94 Two nephrotomies, right and left, at intervals, two pyelotomies, right, for stone, six months after last operation, plain X-ray showed no stone.

Case 50 Double decapsulation.

One case advised to wear a belt and to have nephropexy later if necessary. The patient was also to have dilation of the ureteral stricture.

In 90 cases dilation only was advised, followed by lavage in some instances.

Case 21 Age 26 years, born in U. S., married, male.  
Diagnosis Stricture right ureter, 16 days in hospital.  
Family History Mother had kidney trouble.  
Past History Negative.  
Present History Dull pain in the right kidney region, duration 4 years.  
Symptoms Frequency, nocturia and dysuria.  
Temperature 98 to 102 degrees F.  
Physical Negative, appearance good.  
Urine Negative.  
Cystoscopic No 6 F passed obstruction, 15 cm up, and then to pelvis.  
P S P Negative.  
Microscopic Negative.  
Culture Not done.  
X-ray negative for stone, no pyelogram.  
Treatment and Operation Right ureterotomy. Stricture in lower part of ureter incised and sutured.

Case 25 Age 49, female, housewife, Russian and a widow.  
Diagnosis Congenital malformation of kidney (congenital stricture) 25 days in hospital.  
Family History Negative.  
Past History Negative.  
Present History Dull ache in small of back for 15 years, exercise increases pain.  
Urine Negative.  
Physical Some bad teeth, right kidney easily palpable, floating enlarged and not very painful.  
Cystoscopic Negative.  
P S P Right, 10%, left, 8% in 10 minutes.  
Microscopic Negative.  
Culture Negative.  
X-ray Right kidney large and low, pelvis relatively large, calyces frayed and no stone.  
Treatment and Operation Right nephrectomy.  
Findings at Operation Right kidney very low and normal in appearance, ureter thickened.

Case 29 Age 51, female, Irish, married.  
Diagnosis Pyelonephrosis.  
Family History Negative.  
Past History Negative.  
Present History One year ago urinary symptoms began, frequency, nocturia, dysuria, hæmaturia and strangury.  
Physical Some bad teeth and tender over vesical area.  
Urine Albumen ++  
Pus 1 +  
Blood 1 +  
Cystoscopic Bullous oedema.  
P S P Right, 3% in 10 minutes, left, 10% in 16 minutes.  
Urea Right, 4 grams per litre, left, 10 grams per litre.  
Microscopic Negative.  
G P Negative.

Culture Right, *B. coli*, left, *B. coli* and *B. pyocyaneus*.  
X-ray Right kidney low and pelvis distorted and whole disorganized greatly.  
Treatment and Operation Nephrectomy, right.  
Findings at Operation Right kidney low and slightly enlarged.

Case 31 Age 45 years, male, Italian, married.  
Diagnosis Nephrolithiasis, stricture of left ureter.  
Family History Negative.  
Past History G. C. as youth, 12 years ago severe pain in the left side and passed gravel, right inguinal hernia for the past 6 years.

**Present History** Two months ago sudden pain on the left side radiating to testicle.

**Symptoms** Frequency, slight. Dysuria stream interrupted at times. Sense of something wrong in the bladder for the past 10 years. Flatulence and gas eructations.

**Physical** Appearance good.  
**Temperature** 104 degrees F—chill 4 days post operative.

**Teeth** Fair condition  
Slightly tender over left kidney  
**Urine** Albumen trace. Pus 7 H. P. F  
**Rectal** Negative.  
**Cystoscopic** Negative. No 6 F to pelvis  
P S P 30% 1st hour, 75% 2nd hour  
**Microscopic** Negative.  
**Culture** Negative.

**X-ray** Left kidney, stone in the upper part, large kidney and pelvis, stricture level of body of 5th lumbar vertebrae and just admits a No 6 catheter.

**Treatment and Operation** Ureterotomy and pyelotomy, stone removed and pelvis resutured. Ureter dilated with bougie.

**Case 35** Age 22 years, male, Italian, single.  
**Diagnosis** Hydronephrosis and stricture left ureter, 21 days in hospital.

**Family History** Negative.  
**Past History** "Flu" 4 years ago, nasal operation 6 years ago, pain left side once a week for last 4 years.  
**Present History** Sudden pain left side.  
**Symptoms** Urinary, negative.  
**Physical** Appearance good  
**Temperature** 102 degrees F  
**Urine** Alb plus pus, and blood plus  
**Rectal** Negative.

**Cystoscopic** No 6 to right pelvis, obstr 6 cm. up on left side.

P S P Left appear 10 minutes and only trace.  
**Microscopic** Negative  
**Culture** Negative.

**X-ray** Left kidney hydronephrosis and left ureter relaxed.

**Treatment and Operation** Nephrectomy, left.  
**Findings at Operation** Large kidney and dilated pelvis.

**Exam of Tissue** Moderate round celled infiltration in wall of pelvis and ureter.

**Case 37** Age 52 years, female, Italian, married  
**Diagnosis** Hyper nephroma, fibro-adenoma, 14 days in hospital.

**Family History** Negative.  
**Past History** Hernia operation 4 months ago  
**Present History** Dull backache in kidney region, right, especially for past 3 years.

**Urinary symptoms** Nil  
**Physical** Negative.  
**Urine** Negative.  
**Rectal** Negative  
**Cystoscopic** Negative  
P S P (Right) 204 in 2 hours Bl and left kidney, 14% in 1st hour, 15% in 2nd hour  
**Microscopic** Negative  
**Culture** Negative.

**X-ray** right kidney, 2 small shadows, suggesting stone not seen in X-ray after kidney out. Right ureter, dilated and greatly pushed to left.

**Treatment and Operation** Fibro-adenoma and looks like enlarged prostate.

**Case 41** Age 27 male, U S, single, 14 days in hospital.

**Diagnosis** Ureteritis  
**Family History** Mother had kidney trouble.  
**Past history** Good  
**Present history** Five months ago sudden dysuria,

frequency, terminal hæmaturia, lasted two weeks, and returned 3 weeks ago.

**Urinary Symptoms** Frequency of 20 minutes, nocturia, dysuria and terminal hæmaturia.

**Physical** Good appearance.  
**Temperature** 98 to 100 degrees F  
**Teeth** Fair

**Super pubic region** Slightly tender  
**Urine** Alb trace, pus, +

**Rectal** Negative  
**Cystoscopic** Bladder neck oedematous, superficial ulcer in fundus. Left orifice not distinctly seen for a time. Not catheterized at first. Finally catheterized. Catheter to pelvis.

P S P Appear in 6 minutes, left.  
**Microscopic** Much pus, left.

G P not t.b.c.  
**Culture** Negative.

**X-ray** left kidney negative, lankng at junction of upper and middle third of left ureter, which is dilated and relaxed.

**Treatment and Operation** Left nephrectomy, ureter thickened, adhesions at hilus.

**Examination of Tissue** Left kidney free from inflammatory exudate.

In mucous membrane of upper ureter and pelvis much lymphatic infiltration.

**Case 58** Age 31, female, Russian, housewife. 35 days in hospital.

**Diagnosis** Stricture of ureter  
**Family History** Negative.

**Past History** Negative.  
**Present History** Sudden and sharp pain left lumbar region 9 months ago.

**Urinary symptoms** Nil  
**Physical** Appear good  
**Temperature**, 101 degrees F  
**Post Op** 103.6 degrees F  
**Tender** in left sub-costal region.

**Urine** Alb trace, pus, 15 H P F  
**Rectal** Negative.

**Cystoscopic** Right 6 F to pelvis. Left obstruction 5 cm up and cannot be passed.

P S P Right appearance 3 minutes, 3% in 10 minutes. Left, appearance 18 minutes.  
**Microscopic** Pus, 2 plus, left.

**Culture** Negative.  
**X-ray** Most Sod. Iodode returned to Bladder. Shadow in course of left ureter. Extensive pyonephrosis.

**Treatment and Operation** Left ureterostomy for obstruction.

**Findings at Operation** No stone, ureter much enlarged and when opened much urine escaped. Bougie passed to bladder, and overcame some obstruction.

**Case 94** A. D. female, age 37, U S  
**Diagnosis** Nephrolithiasis. Stricture of ureter.

**Family History** Negative.  
**Past History** Appendix out and uterus lifted, 1915. Left kidney stone out, 1920.

**Present History**  
(1) April 20th to April 21, 1922, 1 day, left pyelogram.  
(2) June 17th to July 9th, 1922, 22 days, right nephrotomy.

(3) Oct. 1st to Nov. 29th, 1922, 59 days, left nephrotomy (stone filling pelvis).

(4) April 22nd to April 29, 1923, 7 days, right pyonephrosis, acute, cystoscopic, 60 cc. drained off.

(5) April 29th to May 20th, 1923, 21 days, right pyelotomy, stone in right kidney (6 stones), dilatation and lavage of 16 days since.

(6) Jan 7th to Jan 26th, 1924, 19 days, right pyelotomy (2 stones), stone 1 to 2.5 cm. in diameter 127 days in all.

Pain began in left side (gradually) 6 months after operation in 1920.

Frequency Every 1 hour for last 2 months, day and night.

Dysuria Haematuria, slight

Gastro intestinal symptoms with 1920 attack.

Physical Fair condition but undernourished. Temperature, 101 degrees F Rectal, negative.

Urine Alb, trace. Pus 2+

Cystoscopic No 5 F to pelvis, after passing whale bone catheter

P S P June 19th, 1922, 5% 1st hour, 17% 2nd hour

Microscopic Pus 2+

X-ray Pyelogram April 21st, 1922 Str upper part Both ureters dilated and relaxed. Multiple stones in both kidneys and right kidney low June 8th, 1924, plain X-ray, no stone.

Case 50 Age 40 years, male, U S, 8 days in hospital, admitted July 12th, 1922, died July 20th, 1922

Diagnosis Acute uremia

Family History Unobtainable.

Past History Unobtainable.

Present History Pain in right side radiating to groin for 1 month

Urinary Symptom Slight frequency Amount small

Physical Slight tenderness over kidneys

Rectal Negative.

Urine Albumen trace, pus few, blood negative.

Cystoscopic No 5 F 20 cm up each side. Very slight flow of urine obtained

X-ray Negative.

Treatment Operation, double decapulation July 18, 1922, 55 minutes under G and O

Findings at Operation Congestion only

Complications Acute uremia developed 48 hours before operation and patient never came out of it.

Autopsy Right ureter, definite constriction about middle.

### CASES NOT UNDERGOING OPERATION

In 90 cases dilation only was advised, followed by lavage in some instances

One case was advised to wear a belt to have dilation of the ureteral stricture, and to have nephropexy later if necessary

The following are the details of six of the cases not undergoing operation.

Case 72 Age 54, female, Italian, married, 13 days in hospital.

Diagnosis Stricture of ureter

Family History Negative.

Past History Left hemiplegia, 1922

Present History Sudden pain right kidney region, 3 months

Urinary symptoms Frequency, nocturia, dysuria and haematuria

Physical Appearance good

Temperature 100.6 degrees F

Systolic at apex and transmitted to left axilla. Right

Costo Vert. angle tender Slight oedema in extremities B P—S-150, D-95

Urine Albumen trace. Pus plus Blood plus

Rectal Negative.

Cystoscopic 6 F to pelvis Right pelvis capacity 8 cc. P S P Right appearance, 5½ minutes, 4%—10 min. Left appearance, 5 minutes, 5%—10 min

X-ray Both kidneys large and low, right pelvis very long and much divided. Right ureter makes a right angle turn mwards towards spine at level of fourth lumbar vertebrae. Below this point is a moderate dilation, and above this point is a very narrow area—definite stricture.

Treatment Dilatation and lavage.

Case 77 Age 44 years, male, U S., married, 5 days in hospital

Diagnosis Str of ureter-pyelitis.

Family History Negative.

Past History G C 1898. Dysentery 1898 and last attack 3 months ago Stones (11 in number), removed from left kidney 1913 and passed another in 1914 Appendix out 1 year ago From May, 1923, to January, 1924, 7 attacks of haematuria and pain.

Present History Gradual onset of pain, for 11 years (along ureter)

Symptoms Frequency, dysuria and haematuria.

Physical Appearance good. Post operation herma at appendix scar and at kidney operation scar

Rectal Negative

Urine Negative.

Cystoscopic Catheter 6 F to pelvis Capacity of right pelvis 30 cc. Capacity of left pelvis, 15 cc.

P S P Appearance right 5 minutes, left 7 minutes, 56% in 3 hours

X-ray Right kidney pelvis larger than usual, right ureter (erect) dilated from upper level of 5 lumbar to B1

No stone. Left kidney double pelvis, which joins in common one, which is dilated. 2 definite shadows.

Treatment Dilatation and lavage

Case 81 Age, 34 years, male, 6 days in hospital.

Diagnosis Stricture of ureter, hydronephrosis

Family History One brother died of peritonitis One brother died of T B C.

Past History G C. 1922 Acute prostatitis May, 1923 Tonsils out May, 1923

Present History Dull pain left side back, gradual for 2 years

Physical Appearance good

Rectal Negative.

Urinalysis Negative.

Cystoscopic Right 6 F to pelvis Left 6 F to pelvis, slight obstruction three-quarters way up

P S P Right appearance, 4 minutes, 7% in 10 minutes Left appearance, 5 minutes, 5% in 10 minutes

Microscopic Negative.

X-ray Left pelvis capacity 23 cc., calyces much stretched out and irregular in outline. Points of constriction No I, 1.1 inches below kidney pelvis, No II, 2.2 inches below kidney pelvis, No III, 1.5 inches above ureteral orifice.

Treatment Dilatation

Case 96 Age 55 years, barber, male, married, 8 days in hospital.

Diagnosis Stricture of ureter

Family History Negative.

Past History Negative.

Present History Sudden pain in left costo vertebral angle and radiating to penis and thigh

Duration 6 days

Urinary Symptoms Dysuria.

Physical Temperature 104 F

Rectal Negative.

Urine Negative.

Cystoscopic Left ureter mouth congested Right ureter No 5 F easily to pelvis Left ureter No 5 F with difficulty to pelvis Pelvis capacity 20 cc.

P S P Right appearance in 3 minutes, trace in 10 minutes Left appearance in 7 minutes, 1% in 10 minutes

Urea Right 40 grms per litre. Left 15 grms per litre.

X-ray Some fraying at level pole left kidney, also at upper and middle parts left kidney Definite stricture from level of transverse process of second lumbar to level of transverse process of third lumbar Dilated above and below this

Case 53 Illustrating obstruction due to pressure, aberrant vessel and not real stricture. Age 44, male, U S., married, 7 days in hospital

Diagnosis Stricture of ureter

Family History Negative.

Past History Cholera in childhood, G. C. and lues  
Present History One and one-half years ago sudden pain left side and to testicle.

Urinary Symptom Nil

Other Symptoms Nausea, vomiting and headaches during attack.

Physical Appearance good Temperature 105, chill, sub-costal tenderness and pain on bi-manual of kidneys

Urine Albumen 2 plus, pus 2 plus, blood 1 plus

Rectal Negative.

Cystoscopic Mild cystitis and trigonitis, No 6 to right pelvis, No 5 to left pelvis

P S P Right appearance in 2½ minutes, 10% in 10 minutes—urea, 25 grams per litre Left appearance in 2 minutes, 8% in 10 minutes—urea, 12 grams per litre.

Microscopic Negative.

X-ray Left pelvis 18 cc.—sod iodide Prone position, 1½ in above crest of ileum Upright position slightly above crest of ileum This makes ureter take shape of right angle in erect position A definite area of constriction can be made out and may be due to aberrant vessel

Treatment Operation later Belt advised for present

Case 74 Case in which hæmaturia was severe and the only symptom Age 56, race U S, male, married, 8 days in hospital

Family History Negative.

Past History Quinsey as child, scarlet fever 15 years old, measles 33 years old

Present History Severe hæmaturia, the onset of which was gradual, and of 8 weeks duration, and which was the only symptom

Urinary Symptom As above.

Physical Patient appears in good health The teeth are nearly all gone, the heart shows an occasional extra systole. The abdomen, lower pole of the left kidney very slightly tender, if at all Blood pressure, systolic 100 diastolic 62

Urine Trace of albumen, abundant blood

Rectal Negative.

Cystoscopic Marked trabeculation, with slight intrusion of the prostate.

P S P Dec. 27, 1923, right appearance 4½ minutes, 15% in 10 minutes Left appearance 4 minutes, 10% in 10 minutes

Jan. 5, 1924, right appearance, 6 minutes, 9% in 10 minutes, left appearance, 5 minutes, 10% in 10 minutes

Urea Right 18 gms per litre Left 16 gms per litre.

Microscopic Right negative, left blood plus plus Granular cast, plus pus

N P N 138

X-ray Left pelvis holds 30 cc. injection fluid, and the outline is feathery A kink of the ureter 1½ inches below uretero pelvic junction, 1 inch below this point ureter much dilated.

#### SUMMARY OF FINDINGS IN THIS SERIES OF CASES

1 The greatest incidence of ureteral stricture, which produces symptoms, is in the 4th decade of life, 33% having occurred at that time in this series Also that the incidence is decreased by one-third approximately in the 3rd and 5th decades, the percentage in these decades having been 23 and 22 respectively, and lastly that it may produce symptoms at any age

2 Sex seems to influence the matter not at all

3 Failure to recognize this lesion and to properly interpret it and treat it results or at

least has in the past resulted, in innumerable useless operations, which of course have followed errors in diagnosis

4 Pain is the most universal symptom, there being only 10% that did not present this symptom, which was the chief symptom in 84 cases

5 Bladder symptoms are very common, inasmuch as they occurred in 60% of cases In 9 cases frequency was the chief complaint In 1 case dysuria was the chief complaint, and in 6 cases the chief complaint was hæmaturia

6 The urine may be quite normal, as it was in nearly half of the cases Hæmaturia may be the only symptom, as it was in 2 of these cases, one of which was very severe The ureteral specimens may be negative also for pus blood and casts, as they were in 81 of these cases The B coli usually is the infecting agent when the culture is positive

7 The fever arises whenever the stricture closes, and this without infection being present

8 Gastro intestinal symptoms are very common having occurred in about one-fifth of the cases

9 Nervous symptoms may be present in a large percentage of cases, there being, however, only 5% in this series This, in fact, may account for and probably does, the great irritability of many persons who appear in good health

10 The physical examination should include palpation of the kidney, and the whole length on the ureter, not neglecting to examine its lower end, per vagina or rectum or both In 43% of cases here analyzed the kidney pathology was made very probable by simple physical examinations

11 Cystoscopy may be quite negative, as only 20% of these cases had cystitis It is the ureter mouth, which is most likely to present pathology, as it may be inflamed, congested, or have a small ulcer near it The fact that a No 6 F catheter passes to the kidney pelvis is no indication that there is no pathology present, as this occurred in 73 cases on the right side and in 64 cases on the left side

12 The Phenolsulphophthalein test and the percentage of urea In roughly one-fifth of the cases here analyzed a difference in the percentage secreted was observed when that from the right was compared with that from the left, the side presenting the greatest lesion, putting out the lesser amount of dye and the lesser amount of urea This is as one would expect, and it probably occurs in all cases, but it is not capable of being demonstrated in all cases, unless one went through more procedures than would be warranted by the patient's condition

13 Definite strictures do occur in all parts of the ureter, and almost as many in the upper

# THE TREATMENT OF CANCER OF THE UTERINE BODY

HAROLD BAKER, M.D. NEW YORK, N.Y.

In the treatment of cancer of the uterus, the use of radium is the most effective method of therapy. During the past few years, the management of the disease has been revolutionized by the use of radium. It is now possible to cure the disease and to preserve the organ in a large number of cases. The use of radium is a relatively new procedure, but it has been found to be of great value in the treatment of cancer of the uterus. In the hands of experts the end result is a good cure with operative measures and the preliminary discomforts eliminated. Moreover, the results have been obtained with only moderate amounts of the substance. These statements, however, do not apply to cancer of the fundus.

Every large hospital and many private individuals possess 100 mg. or more, of radium, and under well controlled circumstances this would be of great benefit to the world but the cheapness of the radium has permitted the untrained man to enter the field of cancer surgery.

Chart 2. Cancer of the fundus. Incomplete irradiation. Malignant adenoma. Extension already in parametrium & that treatment with radium as shown would be of little avail.

Chart 1. Curve showing distribution of irradiation about the platinum tube. (From paper by Harold Baker, M.D., and Edith Quimby. *The American Journal of Obstetrics and Gynecology*, February, 1922.)

A peculiar situation arises. In the first place, if the use of the radium is in the hands of a physician, he seldom has the training in gynecology necessary to allow him to select properly the cases and methods best adapted to the remedy. On the other hand, the gynecologists, with few exceptions, know little of the physics of radium. In all large hospitals a man should be assigned from each branch of surgery, and the

technique best suited to his speciality and in this way we should have experts in charge of irradiation treatments.

The remarks in this paper are in the nature of a warning to the possessors of a small amount of radium, such as 100 or 200 mg., and to men who have not had a complete training in gynecology. Cases have come to my knowledge in which ill-advised applications have been made with expectations of cure far beyond the possibilities.

The action of the radium, from the standpoint of the penetration of the rays is limited and in any amounts that we may safely use, it has a curative action for about 3 cm. from the applicator. The Gamma ray, which is the most suitable for general use, is broken up into secondary rays as it strikes the tissue cells and secondary radiation also comes from the metal of the filter thus causing a slough at the site of the application. Furthermore, the intensity is decreased inversely in proportion to the square of the distance so that any substantial increase in the amount in the capsules does not greatly increase the irradiation of the parametrium, although it causes irreparable damage locally. The capsule form in which we use the radium throws off the rays in such a manner that in any one plane they assume the form of an irregular ellipse and the tissue above and below is not radiated to the same extent as the tissue opposite. (See Chart 1.)

As a result cancer of the fundus can rarely be satisfactorily irradiated as extension of the growth over the dome of the uterus is not reached by the capsules placed in the cavity. Even the side walls may not be sufficiently irradiated be-

Chart 3 Cancer of the fundus. Incomplete irradiation. Papillary adenocarcinoma. Tandem applicators in place. Part of growth not completely irradiated

cause the cavity enlarges with the growth and a tandem of radium placed within falls to one side and may be at some distance from the mucous membrane of the opposite wall (See Chart 2)

The histology of cancer and its method of spreading is also to be considered. The good results in the cervical growths are undoubtedly due to the fact that most of the tumors are of the squamous variety and are slow growing with a tendency to be definitely localized. In the body cancers, on the contrary, the most frequent type is the so-called malignant adenoma which is a rapidly growing tumor of cuboidal and cylindrical cells that extend deeply into the neighboring muscle and may metastasize in as short a time as two months. This type of tumor does not spread over the mucous membrane but rather through the muscle tissue and it is probable that at the time the patient appears for treatment, metastasis into the broad ligament has already occurred and even a very large dose of radium within the uterus will be of little avail. The tumor second in frequency is the papillary adenocarcinoma. This spreads rapidly in the mucous membrane and in-

volves but slowly the muscle wall, even after a period of growth there may be no involvement outside the uterus. In some cases there is a polypoid mass at the fundus that fills such a large part of the cavity that a radium application packed into the uterus may be several centimeters from the top of the growth (See Chart 3)

The lymphatic drainage from the upper part of the uterus passes through the top of the broad ligament to the region of the ovaries and the ovarian plexus and thence to the lumbar nodes at the bifurcation of the aorta, and from the middle part of the uterus, extends to the iliac nodes and may also follow the round ligament to

Chart 4 Cancer of the neck of the uterus. Extension along mucous membrane of parametrium. One of the most malignant types and seldom satisfactorily irradiated.

the inguinal nodes. In the lower part the lymphatics anastomose with those from the cervix and pass to the parametric glands and thence to the iliac nodes. There may also be transfer through the sacro-uterine ligament to the nodes below the promontory of the sacrum.

Cancer of the neck of the uterus does not enter this discussion but it should be stated that this cancer spreads very rapidly into the muscle and through the lymphatics. The cells are usually of the large cylindrical variety and they spread to the lower uterine segment, transfer further than this is through the parametrium to the iliac nodes or through the lymphatics to the ovarian plexus (See Chart 4)

With the knowledge that we have of the two quite different types of adenocarcinoma, it is apparent, that although in the more malignant tumor, the lesion in the mucous membrane is small, there may be lymphatic and glandular extension beyond the uterine wall, and in the papillary type, although the growth is limited to the uterus, it may be so located that with our present form of applicators, we are unable to irradiate it entirely and therefore we must conclude that radium alone cannot be the best method of treating cancer of the uterine body. However, five year results in cases in which radium alone has been used, because other physical conditions rendered operation impossible, show a 44 per cent cure rate which is nearly as high as that accredited to surgery. It would appear, then, that in order to make the most complete use of our facilities, *radium should be combined with surgery in the treatment of cancer of the body of the uterus* (See Chart 5)

There are occasional cases in which cancer occurs in very small areas of the endometrium. These areas are frequently malignant degenerations in a polypoid endometrium and they may be successfully removed by curettage or irradiation. There is one such case on record, in which curettage entirely removed the cancer and there are a number in the literature which have been cured by irradiation. No such simple treatment can be relied upon. The condition within the uterus and the lymphatics immediately adjoining must be unknown to the worker from below and proper treatment requires not only the irradiation but the removal of the organ. Before declaring a specimen free of cancer, many sections from both the uterus and the parametrium must be examined. Our chairman, Dr Beck, has given me permission to mention a case that he is about to report, in which, following preoperative radiation and operation, the uterus appeared to be free of cancer. The pathologist, however, insisted upon cutting repeated sections and finally found a small area of adenocarcinoma. In one of my own cases no cancer was found in the uterus but a small area of degenerated cancer cells was found in the parametrium. If a pathologist reports any pre-cancerous changes such as reduplication or epidermization, or a condition of adenomatous or adenoatoid endometritis, irradiation can be used without operation.

Radium, in treating cancer of the fundus, should be applied in the cavity of the uterus in a

Chart 5 Cancer of the fundus. Incomplete irradiation. Tandem placed in the dilated cavity. Complete irradiation depends upon gravity moving the tandem properly.

tandem in each capsule of which there are 100 mg and irradiation should be for 2,500 to 3,000 millicurie hours depending upon the filter. The best filter is 1 mm of platinum for the larger dose and one-half millimeter of platinum or gold for the smaller dose. Within five days the uterus should be removed by abdominal hysterectomy. At the end of two weeks a series of X-ray doses should be given about the pelvic girdle. This consists of 4 doses of 15 minutes each with 5 mm of aluminum as a filter and at a focal distance of 12 inches. The spark gap should be 10 inches and the kilovolts 90 to 110 with 5 milliamperes of current. In the third week the vault of the vagina should be irradiated by means of a gram of radium given in the bomb applicator and directed toward each sacro-iliac region for one hour.

In conclusion it should be stated that radium alone does not accomplish the best results. The amount of radium required and the exact location in the dilated cavity must be unknown and therefore this agent should not be used without operation.

Irradiation should be given within the uterus before operation so that there is less chance of the disease spreading during operative procedure which should be a simple complete hysterectomy and not an operation of the Wertheim type. Post-operative irradiation should be given at the end of the second week in order that any extension into the lymphatics may be fully controlled. Small in-

stitutions that have only 100 mg of radium will have difficulty in carrying out the treatment for cancer of the body of the uterus as outlined here and therefore certain hospitals should be equipped

to give the complete treatment and cases with this type of cancer should be transferred to those hospitals rather than cared for in smaller institutions

## PREGNANCY AND DIABETES, REPORT OF CASES\*

By BYRON D BOWEN, M D

Buffalo General Hospital, Buffalo, N Y

NOW that death and even marked ill health has been so definitely postponed in well cared for, severe diabetic patients by the use of insulin, and that in these patients physiological processes appear to proceed in quite a normal manner, the advisability for a diabetic woman to become pregnant becomes a question demanding consideration. These individuals who pass in a crowd as being healthy, are not, even though their metabolic defect appears to be stayed, they are still on a diet that is not normal, though it may be sufficient, there may be a disturbance in a vital system, especially the vascular, which is the result of diabetic toxæmia, and they may be more susceptible to certain infections.

Prior to the use of insulin, the occurrence of pregnancy, especially in a severe case of diabetes, was looked upon with alarm, we had not the tools to cope with the situation, and so these patients usually died in coma. With the use of insulin it was only reasonable to expect a better prognosis in such cases. Fortunately the physician does not bear this responsibility in its entirety because pregnancy more often occurs without there having been any previous consultation as to its advisability. In the series of cases reported below we were consulted in but one instance, when consent was given, on condition that the patient be under hospital supervision at least for the last month of gestation. In three of the cases the termination of pregnancy was urged but was refused.

I Whitridge Williams reports that in his group of sixty-six cases of pregnancy in diabetic patients, twenty-seven per cent died during delivery, and twenty-three per cent succumbed within two years following the pregnancy. Also about one-third aborted and one-third of the fetuses were born dead. DeLee's experience was rather similar. This is such a gloomy state of affairs that it is no wonder that pregnancy in diabetics has been frowned upon. Fortunately, however, this condition adjusted itself to some extent, as the large majority of diabetic women became sterile. This is commented upon by DeLee who quotes 114 cases collected by Leconte in whom there were but seven gestations.

Insulin however, has changed this condition, as the majority of amenorrhoeic patients have a return of their menstruation and become fertile. This has recently been discussed by Fitz and Murphy who have reported one case. In our group of seven cases, three had amenorrhoea, with a return of menstruation after prolonged insulin treatment. Joslin, who has had such a complete experience in diabetes, gave his full consent for pregnancy in but one case before insulin. He believes that pregnant women are so unstable that acidosis may come on in a few hours, thereby making it unsafe.

Three cases of true diabetes and pregnancy have recently been reported by Strouse and Daly. Two of them were apparently mild and were delivered of healthy babies without difficulty, in the other there was diabetic coma, and while the mother was saved by insulin, the child was born dead.

The following small series is composed entirely of cases of true diabetes mellitus. There are, to be sure, many glycosurias complicating pregnancy that are not truly diabetic, these of course should be carefully differentiated, if necessary, by sugar tolerance tests which will usually decide whether the glycosuria is of the diabetic, renal, or the alimentary type. It is most important that this decision be made before intelligent advice can be given.

Case 1—Mrs M P, age 33, File No 20342, was first admitted to the hospital on January 29th, 1923, because of diabetic symptoms which had been going on for three years, during which time she had lost sixty pounds in weight. Physical examination did not reveal any abnormality. Her urine contained plenty of sugar but no ketones. The blood sugar was 290 mgms. She was placed on a diet of about 1,000 calories, whereupon the urine immediately became free from sugar, later on it was determined that she could tolerate a diet of C 45, P 50, and F 150 without glycosuria, but with moderate hyperglycaemia—150 to 230 mgms. The weight remained about the same—98 to 100 pounds—so that after a month of treatment with diet alone, insulin was started—five units before meals. She was discharged on April 20th, taking a diet of C 60, P 60, and F 160, with seven units of insulin before each meal. Her weight was 109

\* Read in abstract, before the Eighth District Branch of the Medical Society of the State of New York, October 1926.

pounds She was seen thereafter frequently in the Diabetic Out-patient Clinic and continued to gain weight and improve generally During November 1923 she was found to be about two months pregnant She was seen at least every two weeks during her pregnancy, her blood sugar was usually normal and the urine sugar free The weight increased to 152 pounds The blood pressure remained normal—102 to 108 systolic and 76 to 84 diastolic

*Second Admission*—On May 3rd, 1924, she was admitted in a state of pre-coma, there was very marked hyperpnoea and evidence of dehydration It was learned that she had been vomiting for two days The urine contained a good trace of albumin, no sugar, a sodium nitro-prusside reaction, and the sediment showed a few granular casts The blood sugar was 160 mgms and the CO<sub>2</sub> capacity of the plasma was 65 mm Her blood pressure was 140 systolic and 75 diastolic She was given a hypodermoclysis of 500 cc of salt solution, and a 5 per cent solution of glucose combined with 2 per cent solution of sodium bicarbonate was administered per rectum Vomiting continued and the following day she was considerably worse—the pulse had risen from 100 to 138, and she was in a state of partial collapse Hypodermoclysis was repeated and 200 cc of a 10 per cent solution of glucose was given intravenously, one-half hour before which she had received 15 units of insulin Also, caffeine sodium benzoate 0.5 was given subcutaneously Two hours later 200 cc of a 10 per cent solution of sodium bicarbonate was given intravenously A Caesarean section was decided upon and at the time of the operation—8 p m—which was performed by Dr William T Getman, the patient was in such a state of collapse that it was easily performed under local anaesthesia The patient rallied very quickly after the uterus was emptied, and the breathing was easier, probably because of the removal of the hindrance to respiratory excursion The child was alive and weighed nine pounds and two ounces The patient continued to vomit for two days so that no appreciable amount of food was retained, hypodermoclysis of salt solution, and glucose per rectum had to be resumed On May 5th the CO<sub>2</sub> capacity of the plasma was 27 mm, the blood sugar was 255 mgms and the urea nitrogen in the blood 49 mgms per 100 cc. The urine contained a +++ albumin reaction, a ++ sugar, and a slightly positive ferric chloride reaction From then on the patient improved and was given regular trays on May 8th She and the child were discharged on June 14th in excellent condition The mother's blood sugar was normal—133 mgms—the blood urea nitrogen was 15 mgms and the urine contained neither sugar nor albumin Her weight was 125 pounds She

was again followed in the Diabetic Out-patient Clinic although she did not report as regularly as before Her weight increased considerably so that a year later it had reached 170 pounds The urine was free from sugar, except for an occasional trace, but the blood sugar was frequently high—171 to 230 mgms In July, 1925, it was found that the patient was again pregnant Intervention was advised but she refused On December 22nd her weight was 188 pounds, the urine was free from sugar and the insulin dosage was 13 units t. i. d

*Third Admission*—On February 23, 1926, she was again admitted in a pre-comatose state, much the same as in the second admission but not as severe She had been vomiting for two days and had had headache and swelling of the lower extremities The urine contained albumin (++) , a trace of sugar and a +++ ferric chloride reaction The blood sugar was 328 mgms and the CO<sub>2</sub> capacity of the plasma was 74 mm Her blood pressure was 100 systolic and 60 diastolic She was seen immediately in consultation with Dr Francis C Goldsborough and an immediate Caesarean section was decided upon, because of our previous sad experience of waiting twenty-four hours Salt solution was administered subcutaneously and a glucose and sodium bicarbonate solution per rectum She was given 10 units of insulin just prior to the operation which was performed under nitrous oxide and oxygen anaesthesia By previous consent the Fallopian tubes were tied at the time of the section She improved immediately after the operation as she had done the previous time

The child weighed five pounds and ten ounces and lived but eight hours after the section Necropsy showed an incomplete development of the brain, external hydrocephalus, and petechial haemorrhages in the meninges, pericardium, and pleurae Unfortunately the pancreas was not examined The chief diagnosis was prematurity

On March 12th insulin was discontinued for seventeen days during which time she was taking a diet of C 60, P 60 and F 130 Sugar did not appear in the urine even in traces despite the high blood sugar (266 mgms) on March 26th She, nevertheless, was discharged with insulin—12 units in the morning and 10 units at night Her weight was 155 pounds

*Comment*—Two pregnancies in a moderately severe diabetic patient, both terminating rather suddenly in acidosis and coma which appeared to be diabetic, except for the absence of glycosuria In the first instance the symptoms became progressively worse despite treatment until the uterus was emptied In the second instance Caesarean section was done immediately with little preparation The child at the last section died because of prematurity

Case 2—M T, a stenographer, age 22, File No 21003, was admitted to the hospital May 16, 1923, because of diabetes. The usual symptoms had been present about eighteen months, and during some of this time she had been upon a diet which had failed to control the sugar. Her history was unimportant except that an uncle also had diabetes. Her height was 60 inches and her weight 96 pounds. Her blood pressure was 110 systolic, and 60 diastolic. Physical examination was negative, except for the poor nutrition. The urine contained albumin, +, sugar, +++, the ferric chloride reaction was +++, and the sediment showed a rare hyaline cast. The blood sugar was 170 mgms and the blood urea nitrogen was 23.8 mgms per 100 cc. She was discharged from the hospital on May 31st, taking a diet of C 60, P 50, and F 140 and insulin 10 units before meals. The urine sugar was reduced from 46 grams in twenty-four hours to a trace and the ferric chloride reaction had become negative. She was seen occasionally in the Diabetic Out-patient Clinic up to October, 1923, during which time the urine remained free from sugar and the blood sugar varied from 100 to 180 mgms. Her insulin dosage was increased to 12 units before breakfast and supper and 8 units before lunch. Her weight increased to 107 pounds. The patient was not seen again until her second admission.

*Second Admission*—On December 5th, 1925, she was re-admitted, seriously ill, at which time she was seen with Dr William T Getman. Her pregnancy was nearly at full term. There had been oedema for ten weeks which was increasing. Headache and vomiting had been present for several days. (It was learned from her physician that the urine had remained sugar free all during the pregnancy but that albumin had appeared during the past few weeks.) The urine contained albumin, +++, sugar 0, a slightly positive ferric chloride reaction, and the sediment contained many granular casts. The blood urea nitrogen was 28 mgms, chlorides (whole blood), 453 mgms, sugar 180 mgms, and the CO<sub>2</sub> capacity of the plasma was 14.3 mm. The blood pressure was 180 systolic and 100 diastolic.

The membranes were not ruptured. It was decided to induce labor and a bougie was inserted. During the night the patient received a 3 per cent solution of sodium bicarbonate by rectum and orange juice by mouth, there was some vomiting. A venesection was done and 350 cc. of blood removed. Also, morphine sulphate 0.1 was given subcutaneously in 40 cc. of a 28 per cent solution of magnesium sulphate. By morning (December 6th), the patient having gotten considerably worse, and no labor pains

having occurred, Caesarean section was decided upon.

Before the operation the patient received 15 units of insulin followed in a half hour by 200 cc of a 10 per cent solution of glucose intravenously. The section was performed under nitrous oxide and oxygen anaesthesia and she was delivered of a ten pound child. It was impossible to resuscitate the child. The mother did not regain consciousness after the operation. Salt solution was given intravenously, oxygen inhalation through nasal catheters was kept up, caffeine sodium benzoate 0.5 was administered subcutaneously every hour, and finally, about 200 cc of blood was transfused. Death occurred in about two hours after the patient returned from the operating room.

*Comment*—This patient entered the hospital in a seriously ill state, with an association of rather severe diabetes, and a toxæmia of pregnancy, probably eclamptic. The induction of labor failed and twenty-four hours of valuable time were lost. Caesarean section was done but both the mother and child died. It is possible that if insulin and glucose were given immediately and Caesarean section resorted to earlier, that the outcome might not have been so tragic.

Case 3—H R, a housewife, aged 36, File No 31,947, was admitted to the hospital on February 18th, 1925, because of diabetic symptoms which had been present for about two years. Her weight during that time had dropped from 160 to 102 pounds. She was the mother of five children and had had one stillbirth. Physical examination was negative excepting for the poor nutrition. X-ray examination of the lungs showed an increased density in the upper lobes of each lung, which might be produced by tuberculosis. The urine contained 26 grams of sugar during the first twenty-four hours and a ++ ferric chloride reaction. The blood sugar was 220 mgms. She was discharged from the hospital on March 5th, with a diet of C 50, P 60, and F 130 and insulin, 10 units night and morning. During May, 1925, we learned that she was pregnant. She remained well all during that period, her blood sugar was always normal (weekly examinations) and the urine free from sugar and albumin. Her blood pressure also was normal—about 120 systolic, and 80 diastolic. On October 12, 1925, she was delivered at home of a healthy, six pound child, by Dr Victor A. Pchellas. She returned to the Diabetic Out-patient Clinic again in November in very good condition and weighing 121 pounds. Her urine remained free from sugar at all times, and it did not appear that the pregnancy affected her tolerance in the slightest. On June 1st, 1926, she came to the clinic and it was found that her digestion blood sugar was 350

mgms, and that the urine contained sugar, upon inquiry, however, it was learned that she had forgotten to take her insulin that morning. She had been frequently cautioned against subsequent pregnancies, but nevertheless, when she visited us in August it was announced that she was again pregnant—one month.

*Comment*—Although this patient appeared to be a moderately severe diabetic, she went through a pregnancy without the slightest disturbance. The foetus, however, was small.

**Case 4**—R D, aged 33, File No 36,291, was first admitted to the hospital October 24, 1925, because of diabetes, the symptoms of which had been present for about six months. During this period her weight had dropped from 250 pounds to 228. One sister who is also obese has diabetes. She has had six pregnancies, four of them having terminated in a miscarriage, the two children are in good health. Physical examination revealed an obese woman with rather pale skin and mucous membranes. The tonsils were large and showed large crypts. The blood pressure was 110 systolic and 70 diastolic. There was no oedema. The urine showed the slightest possible trace of albumin, a + sugar, and a faint ferric chloric reaction, the sediment showed numerous white cells, but no casts. The blood sugar was 170 mgms. The haemoglobin was 70 per cent and the red cells were 4,600,000. The white cells (on one occasion) were 13,800 and the differential count showed 60 per cent of polynuclear cells. The Wassermann reaction in the blood serum was negative. She was placed immediately upon a diet of about 1600 calories and immediately the sugar disappeared from the urine. She was discharged from the hospital on October 30th with a diet of C 50, P 70, and F 130. Her blood sugar (digestion) was 164 mgms. Her weight was 217 pounds. She was followed in the Diabetic Out-patient Clinic, her weight dropped slowly—one to two pounds a week—and her urine remained free from sugar. It was then learned that she was pregnant.

*Second Admission*—On December 12th, 1925, she was re-admitted because of vomiting which had persisted for nearly four weeks. The urine showed considerable sugar—186 grams the first 24 hours—there was, however, only a slightly positive ferric chloride reaction. Unfortunately the blood sugar or the CO<sub>2</sub> capacity of the plasma were not done before treatment was instituted. A two per cent solution of sodium bicarbonate was given per rectum. Insulin 8 units every six hours, one half hour before a feeding of 200 cc of milk. Vomiting stopped immediately. On the third day after admission she was able to take trays and insulin was discontinued. She, however, took only about 75

per cent of her diet. Her weight on December 20th was 182 pounds. The urine contained only the faintest trace of albumin with but a few white cells in the sediment. She was discharged on December 24th in fair condition. Her blood sugar (digestion) was 80 mgms.

She was seen again in March, 1926, at which time the urine showed a trace of albumin, no sugar, negative ferric chloride reaction and a few round epithelial cells in the sediment. Her weight was 188 pounds. The blood pressure was 110 systolic and 75 diastolic. She was then six months pregnant. Again, in May, there was no essential change in her condition, except that no albumin was found in the urine.

During June she was delivered at home by Dr John A Metzen, there were apparently no complications. The child was alive and weighed six pounds. At her visit to the clinic in August the blood sugar was 83 mgms and the weight 163 pounds. She felt well.

*Comment*—A rather mild diabetes in an obese woman, which apparently became milder as her weight was reduced. Vomiting of pregnancy occurred during the third month of gestation which cleared up quickly, after she came to the hospital for treatment, and gave no further trouble.

**Case 5**—E B, aged 24, File No 40,776, was admitted to the hospital on July 3rd, 1926, because of pregnancy (7 months) and diabetes which latter had existed for an indefinite time. She had visited a physician three years previously because of an irritation of the vulva, sugar was found in the urine. At that time her weight was at its highest—225 pounds. The mere omission of sugar from diet, according to her statement, caused the sugar to disappear, it returned, however, as soon as a normal diet was taken. She had had four previous pregnancies, the last one resulting in a miscarriage which occurred in October, 1925. Two of these, the first and third, were instrumental deliveries and at the third the child weighed thirteen pounds. At each pregnancy, especially the second, she had suffered from marked anaemia both during the period of gestation and for some time afterwards.

Physical examination showed an obese woman weighing 216 pounds. Her skin and mucous membranes showed a moderate pallor. There was an icteroid hue to the sclerae. The blood pressure was 128 systolic, and 86 diastolic. There was slight oedema of the legs, and slight dyspnoea. The urine contained a ++ albumin, 8 grams of sugar during the first 12 hours in the hospital, a + ferric chloride reaction, and the sediment showed many white and epithelial cells. The blood sugar was 227 mgms, and the urea nitrogen 98 mgms. The haemoglobin was 69 per cent. The white cells were 9,200 with

75 per cent of polynuclear leucocytes. The Wassermann reaction in the blood serum was negative. The van den Bergh test gave a negative direct, and a slightly positive indirect reaction. For the first two days of her stay she received 5 units of insulin every five hours, one-half hour after which she was given orange juice, 200 cc, combined with the whites of three eggs. Sugar disappeared from the urine (except for an occasional trace) after the second day when she was placed on a regular diabetic diet—C 60, P 90, and F 100. Insulin was then discontinued. The blood sugar on July 9th, was 175 mgms during digestion, on the 12th, it was 143 fasting. She was discharged from the hospital on July 14th. When seen again, on July 31st, her weight was 219 pounds. Blood pressure 135 systolic and 80 diastolic. The urine contained a ++ albumin, a trace of sugar but a negative ferric chloride reaction. The blood sugar was 162 mgms.

*Second Admission*—She was readmitted on August 29th in labor. Her membranes were ruptured although there was no pain. Her blood pressure was 150 systolic and 120 diastolic. Other examinations were about the same as upon previous occasions. She was delivered quickly (15 minutes) by version and extraction, under chloroform anaesthesia by Dr Irving W Potter.

The child weighed ten pounds and ten ounces and appeared perfectly healthy. On September 3rd, the mother's haemoglobin was 45 per cent and the red cells were 2,800,000. The white cells were 6,500 with 70 per cent of polynuclear leucocytes.

*Comment*—A rather mild diabetes occurring in an obese woman. Pregnancy progressed normally and she was delivered at full term by version and extraction. Both the mother and child did well. A rather marked secondary anaemia was the only complication.

*Case 6*—H B, aged 34, File No 17,943, was admitted to the hospital on October 26th, 1922. She stated that diabetic symptoms came on in June, 1920, during the early months of her second pregnancy. She had remained on diabetic diet and had gone through the pregnancy without any disturbance. Two months after its termination while on a fairly liberal diet no sugar was found in the urine, but later the symptoms returned so that it was necessary for her to diet quite strenuously. During that two year period her weight dropped from 165 to 116 pounds. She had had an attack of kidney stones six years ago and one attack one year later. During the year of 1919 she had two attacks of maxillary sinusitis. Her paternal uncle died of diabetes at 48 and her father died suddenly at 62 of "heart disease." Her mother died of pernicious anaemia at 60. Physical examination showed a

slightly undernourished woman with some pallor of the skin and mucous membranes. The accessible arteries and veins appeared slightly more firm than normal. The blood pressure was 100 systolic, and 70 diastolic. The right kidney was palpable but not tender. The urine showed the faintest trace of albumin, a heavy sugar reaction and a positive sodium nitro-prusside reaction, in the sediment, numerous white blood cells. The haemoglobin was 82 per cent, red cells 4,980,000, white cells were 4,800 with 71 per cent of polynuclears. The Wassermann reaction in the blood serum was negative. The admission blood sugar was 370 mgms, and the CO<sub>2</sub> capacity of the plasma was 29 mm. The first twenty-four hour urine specimen contained 68 grams of glucose. She was placed on a diet of 850 calories, at the end of a week 27 grams of glucose was excreted in a day. Insulin was then started—20 units per day (she being one of our first patients to receive it). She was discharged on November 18th, with a diet of C 45, P 50, and F 115 with 40 units of insulin daily. The urine was free from sugar and diacetic acid and the blood sugar was 130 mgms. Her weight was 109 pounds. She was seen frequently from time to time after leaving the hospital and her case proved to be a difficult one, because on the one hand she had rather distressing insulin reactions and on the other marked glycosuria. Her diet, on December 17th, was increased to about 1,650 calories. Her weight increased rapidly and in a year had reached 156 pounds.

*Second Admission*—She came to the hospital again on December 3rd, 1923, for a check up, because it had been so difficult to get the sugar under control, and for a rest. It was learned that her menstruation, which had been absent since December, 1921, had returned normally in July and August, 1923, but had since ceased again. She was discharged on December 8th, receiving a diet of C 48, P 70, and F 124, with 28 units of insulin in the morning and 22 in the evening. Her urine, on that program was sugar free at all times and the blood sugar was quite normal during digestion. While at home she continued to do well, but had to have the dosage of insulin increased about 10 units to control the glycosuria. During the summer of 1924 she consulted us with regard to advisability of becoming pregnant. She was told that nothing could be guaranteed but if she kept under strict supervision and if she would remain in the hospital during the last month that her life would not be greatly endangered. To this she acquiesced. During this pregnancy she reported frequently and remained free from any signals of danger, although the blood sugar was high at times—225 mgms. Her weight increased tremendously, reaching 182 pounds in April, 1925.

The abdomen was huge. The blood pressure was always normal 115 systolic, and 85 diastolic. The urine was generally free from sugar and no positive ferric chloride reaction was ever obtained. The insulin had to be increased to 36 units in the morning and 32 in the evening.

*Third Admission*—On May 29th, she was admitted to the Children's Hospital at full term. She was delivered immediately by version and extraction by Dr Irving W Potter, under chloroform anaesthesia. There was a very marked hydramnios. The child weighed ten pounds and appeared well, excepting for cyanosis, which was attributed to the rather long labor. After the delivery she was given 15 units of insulin and in a half hour, 200 cc of orange juice. The child developed increasing cyanosis, had muscular twitching and did not breathe well. Oxygen inhalations, calcium by mouth, and subcutaneous injections of atropine sulphate—1/2000 gr were of no avail and death took place in eight hours. A necropsy was not permitted. The mother did splendidly except that she appeared to be extremely sensitive to insulin after delivery, so that the dose, finally on discharge, ten days later, had to be reduced to 24 units in the morning and 10 units at night. The diet remained the same.

*Comment*—Pregnancy in a very severe, long standing case of diabetes that required 70 units of insulin daily during the gestative period. There were no complications directly attributable to the diabetes. There was marked hydramnios and a large child which lived only eight hours. After delivery the insulin dosage had to be reduced 50 per cent in order to avoid severe reactions.

Case 7—R. H., aged 28, File No 25,302, was admitted to the hospital on January 14th, 1924. She stated that diabetes had come on three years ago and since that time she had had complete amenorrhoea. She had been in the Physiatric Institute at Morristown, N. J. for two months during the Spring of 1923 and since that time she had received insulin about 70 units a day. Her diet was about 1800 calories and during the time of insulin treatment her weight had increased 20 pounds, so that now it is 134 pounds. She had had one normal pregnancy but the child died about a year prior to the onset of the diabetes.

Physical examination was not remarkable except that both the ankle and knee jerks were absent. The blood pressure was 105 systolic, and 70 diastolic. The haemoglobin was 75 per cent. The urine was negative except for a trace of sugar in the forenoon specimen, there was no diacetic acid. The blood sugar was always low—about 100 mgms—taken during digestion. She was discharged from the hospital on Janu-

ary 19th, with a diet of 1,500 calories and 22 units of insulin before meals. In April, 1924, she had a return of menstruation. The weight increased steadily and in May it had reached 168 pounds. Her home arrangements were such that she could not conveniently weigh her diet so that she often had insulin reactions or showed marked glycosuria, it is probable that she overate at times. In June she suspected pregnancy as there had been no further menstruation, this suspicion was confirmed by her obstetrician. Her weight increased tremendously and in December was 189 pounds. The urine showed an occasional trace of albumin, usually contained sugar and a trace of diacetic acid, but there was nothing abnormal in the sediment. The blood pressure was always normal.

*Second Admission*—On December 11th, 1924, she was admitted to the Obstetrical Service of Dr William T Getman, in labor, the child which was nearly two months premature was delivered spontaneously. It weighed five and three-fourths pounds and lived only three days with an increasing jaundice. Necropsy showed multiple haemorrhages in the lungs, serous membranes, and spinal dura, slight gastric and duodenal catarrh, oedema of the lungs. The chief diagnosis was icterus neonatorum. The mother was discharged on December 21st. She was strongly advised not to become pregnant again. During the next few months she visited us rarely. On March 28th, 1925, her weight was 177 pounds and the fasting urine showed a +++ sugar reaction and a + ferric chloride reaction. She was still careless about the diet, but continued the insulin. On July 14th, 1925, she came in and announced that she had "felt life" for two weeks. At that time her weight was 185 pounds. She had increased the insulin dosage to 96 units per day. The urine was free from sugar, albumin and diacetic acid and the blood sugar was 63 mgms. She wished to continue the pregnancy and promised faithfully to test the urine for sugar several times daily.

*Third Admission*—On July 28th, 1925, she was admitted with symptoms of impending diabetic coma. There was vomiting and marked hyperpnoea which had been present for about six hours. It was learned that she had omitted the last dose of insulin because the supply was exhausted, symptoms came on soon after. Her rectal temperature was normal, the leucocytes were 17,000 with 85 per cent of polynuclears. There was no discernible infection. The urine was loaded with sugar and diacetic acid and gave a +++ albumin reaction, but no casts were found in the sediment. The blood sugar was 512 mgms, urea nitrogen 17.5 mgms. The CO<sub>2</sub> capacity of the plasma was 5 mm. She was treated in the usual manner with insulin, 15 grams of sodium bicarbonate, and fluids, with

the result that she improved rapidly. On July 30th, she aborted a five months, dead foetus. She was discharged on August 8th, with a diet of C 50, P 70, and F 90. Her weight was 172 pounds. Insulin dosage, 50 units per day. She then moved out of the city and was lost sight of until her next admission.

*Fourth Admission*—She was re-admitted on December 14th, 1925, three months pregnant, for the purpose of having the pregnancy terminated, which we had insisted upon. This was done without difficulty and she was discharged on December 20th. She has not been seen professionally since and as far as we know there have been no more pregnancies.

*Comment*—A very severe diabetes in a young woman who had a return of menstruation, after a three years' cessation, as a result of insulin treatment. She became pregnant three times, the first resulted in spontaneous labor at the end of seven months, the child dying in three days, the second terminated in a miscarriage (5 months) two days following diabetic coma, and the third was interrupted artificially at the third month. The patient apparently did not suffer any permanent harm as the result of her experience, despite the fact that she had taken poor care of herself.

#### DISCUSSION

Of the seven cases reported, five required insulin before, during, and after pregnancy and therefore must be classified as severe cases. Two of them were especially so, as their insulin dosage was large. In these five cases pregnancy would have been impossible without insulin as the diabetes was of several years duration. The two patients who did not need insulin were obese, in the obese stage of diabetes insulin is rarely required, as the tolerance remains good until a great amount of weight is lost.

Case 1 is especially instructive, and it brings up a few questions of both academic and practical interest. A severe aglycosuric ketosis and acidosis came on rapidly and assumed violent proportions near the end of two successive pregnancies. There had never, on repeated examinations, been any glycosuria, and the diet while it was higher than the usual normal in fat, it was well within the accepted ketogenic and anti-ketogenic ratio, which is considered safe. It is possible that there might have been an element of toxæmia of pregnancy, as in the first pregnancy treatment appeared to be of no avail until the uterus was emptied, in the second we did not wait but terminated the pregnancy immediately. There was, in both instances, albumin and casts in the urine, this, however, is the classical accompaniment of any severe acidosis and cannot be considered as especially indicative of eclampsia as it had not been present

until the acidosis came on. The blood pressure was slightly elevated—140 mm systolic at the first attack, while it was normal at the other. In case 7 there was also an acidosis and coma, this, however, was easily explained as there was marked glycosuria and hyperglycaemia. The patient had been very careless about her diet and had neglected to take one dose of insulin. These cases demonstrate how extremely sensitive these pregnant diabetics are to acidosis, and how treacherous it may be. In normal pregnancy there is a slight acidosis, usually, if we may take the depletion of the alkali reserve as a criterion, the  $\text{CO}_2$  capacity of the plasma is usually about 25 mm. and not infrequently as low as 20 mm. Possibly this may be a factor in explaining the susceptibility.

Case 2 demonstrates a true eclamptic toxæmia in a severe diabetic, who had during her pregnancy been rather careless about dieting although she had kept up the insulin. Nevertheless, upon admission to the hospital, even though she was in a critical condition, the diabetes did not appear to be a prominent feature, as there was no glycosuria or ketonuria and the blood sugar was only slightly elevated. Induction of labor failed and later Caesarian section was resorted to, but the result was a very unhappy one—both the mother and child died. Prompt section in this case might have led to a more favorable outcome.

Hydramnios, which was quite marked in Case 6, is claimed by Grafe to be more frequent in diabetic mothers.

Colorm has reported that 19.5 per cent of the fetuses of diabetic mothers were oversize. In this group, those of whom went to term, weighed respectively 9 pounds and 2 ounces, 10 pounds, 6 pounds, 7 pounds, 10 pounds and 10 ounces, and 10 pounds.

In this series of seven cases there have been ten pregnancies, two of which were miscarriages. Of the eight that came to term, or nearly so, four of the children were either born dead or died shortly after delivery. One of the mothers was lost, not directly as a result of diabetes, although that might have been a contributing factor. The mother in one case was in a critical condition on two occasions so that considerable apprehension was felt.

It is very difficult to decide whether pregnancy affected the tolerance. Cases 1, 6 and 7 demanded some increase in the insulin during pregnancy to control the carbohydrate metabolism, this quite probably might be attributable to the marked increase in weight that took place in these three patients. In these patients, after the termination of pregnancy, we were able to reduce the insulin considerably.

This experience was unexpected because of the experimental work of Carlson and Ginsburg who

found that complete pancreatectomy in pregnant bitches near term is not followed by hyperglycæmia and glycosuria as long as the foetuses are alive and the placental connections are not severed. These workers observed that full evidence of diabetes, such as occurs when pancreatectomy is done on non-pregnant dogs, did not appear until after the birth of the foetuses. They thought that secretion from the foetal pancreases reached the maternal circulation, thereby protecting the mother against diabetes.

While it is beyond the intention of this communication to discuss this subject from the standpoint of eugenics, we cannot be unmindful of the possibility of increasing the number of diabetics by the sanctioning of diabetic mothers to bear offspring. That diabetes runs in certain families cannot be gainsaid, every physician with an extensive diabetic practice has numerous case records of notable diabetic families, although the majority, particularly those who are severe, often do not have a positive family history. Two instances of simultaneous diabetes in the mother and foetus have recently been reported, one by Ambard *et al.*, and the other by Merklen, Wolf and Oberling.

#### SUMMARY AND CONCLUSIONS

1 Diabetes complicated by pregnancy, particularly if the diabetes be mild, can be carried through successfully if the patient is kept under the strictest supervision. This may be impossible.

2 Acidosis and coma may arise suddenly

even though the patient is kept free from glycosuria. Such a possibility is always ground for apprehension.

3 In the event of serious complications the pregnancy should be terminated immediately, preferably by Caesarean section.

4 The foetal mortality is apparently high.

5 Pregnancy, especially in the severe diabetic patient, is still a somewhat hazardous undertaking, and aside from the standpoint of eugenics and human economics, should be considered very seriously.

### PUBLIC HEALTH PROGRESS IN TWENTY-TWO COUNTRIES\*

By ELIZABETH PARKHURST, A.B., ALBANY, N. Y.

Research Assistant, Division of Vital Statistics, New York State Department of Health

THE International Health Year-Book, the first annual "progress report" published by the Health Organization of the League of Nations is a summary of public health activities during 1924 in twenty-two countries. The United States and Canada are included, but with these two exceptions it is entirely a European report. One notes with surprise the absence of Great Britain, Ireland, and Italy.

Handbooks dealing with the organization of public health activities in different countries have already been published by the League, or are in the process of preparation. Since progress in the field of Public Health is rapid, the purpose of the Year-Book is to supplement this information by giving a comprehensive survey of important developments each year.

The information for each country falls into the following subdivisions:

- I General Introduction, giving population, birth, death, and infant mortality rates.
- II Recent Developments in Health Administration and Legislation.
- III Preventive Medicine and Hygiene.
- IV Curative Medicine.
- V General Problems (varying from public health propaganda to the housing question).

The stress laid on each of these topics varies according to conditions in the several countries. In Greece, for example, the problem of social and economic adjustment is of paramount importance. The forced removal from Turkey of hundreds of thousands of Greeks, together with considerable immigration of Greek and Armenian refugees

\* Review of International Health Year Book, 1924. League of Nations. Health Organization. Geneva 1925.

from Bulgaria and southern Russia, has proved a heavy drain upon the limited resources of the country. The unfavorable circumstances in which these newcomers were forced to live made outbreaks of disease inevitable and measures of prevention and control difficult.

The countries represented in the Year-Book may, broadly speaking, be divided into four groups:

Neutral countries in which the scope and character of health activities were not seriously disturbed by the World War.

Belligerent countries, like France and Germany, which have resumed activities interrupted by the War.

Other belligerent countries which have not as yet completely recovered from the effects of the War. They are still obliged to concentrate their energy in combating epidemic and infectious diseases—an aftermath of the War years.

And, finally, countries which were born or resurrected after the peace of Versailles and in which public health work is only beginning. In Yugoslavia (the Kingdom of the Serbs, Croats, and Slovenes), for example, "the most serious difficulty is clearly due to the fact that the general intellectual level of the population is extremely low and that the people are totally ignorant of any rules of social or individual hygiene." Public health in such a country cannot, therefore, be expected to be so comprehensive as in a country with a long established health organization.

*Births, Deaths and Infant Mortality*—Statistics of births, deaths and infant mortality are given for all countries except the Kingdom of the Serbs, Croats, and Slovenes. The year for which the figures are given varies and for some countries (France, Finland, and Rumania) only totals, not rates, of births and deaths are given. The latest figures for France are for 1919, Austria, Belgium, Czechoslovakia, Estonia, and Greece give figures for 1923, and the rest of the countries for 1924. Greece gives rates based upon data for the ten most populous towns, Poland has statistics for three provinces and the larger cities only.

When the figures are compared, one notes the very low infant mortality rates of the Scandinavian countries, and the high rates of Russia, Bulgaria, Hungary, and Czechoslovakia. The rates in Russia were, however, higher before the War than they are now, in Moscow the infant mortality has dropped from 268 to 163 deaths under 1 year per 1,000 births, and in Leningrad from 247 to 138. Infant mortality rates in general are

difficult to compare, because of the unlike definitions of a stillbirth. In some countries infants who die within several hours, or even days, after birth are not included in the infant mortality. General death rates have declined greatly since the War in all countries.

*Epidemic and Infectious Diseases*—A record of the prevalence and methods of control of the more important epidemic and infectious diseases is given for each country with comparative data for other years. The venereal diseases, tuberculosis, and cancer receive special attention. The statistics are seldom comparable, since the degree of completeness of reporting of cases cannot be determined, and death rates are seldom given. However, the whole presents a good picture of the relative importance of these diseases in each country, and the progress that has been made in their control. Mortality from tuberculosis has declined, though in Hungary, Poland, and Austria the rates are still very high: 400 per 100,000 population in Budapest in 1924, 300 in Hungary as a whole, 255.1 in Warsaw, 350.4 in Lwow, and 205.9 in Austria. While the rate in the whole of Latvia is only 117, in Riga it is 214. These are astonishingly high when set against the rates in western Europe and the United States. In 1924 the rate in the State of New York was only 94.

A table of mortality from cancer in Warsaw in the last forty years shows the very interesting fact that, contrary to the experience of other countries, the death rates from cancer have not increased. No explanation is offered, but statistics for other large cities of Poland similarly show no increase, the rate in Lodz having decreased considerably in the last five years.

*General Problems*—The budget for health is usually given, sometimes in bewildering detail. The number of doctors and medical students, nurses and midwives, hospitals and laboratories, depict the public health equipment of each country. The control of foodstuffs and biological products, housing, sewerage and drinking water, physical education, the cost of living, all receive consideration.

The first issue of the report is, as published by the Health Organization, necessarily in the nature of an experiment, and a second will undoubtedly show changes in content and treatment. The reports for the most part are clear and concise, and the volume is well indexed. The Year-Book is an important contribution to current international public health literature, and as such is of value to people interested in the health of all members of the human family.

## LEGISLATIVE COMMITTEE'S REPORT ON CHIROPRACTIC

The joint legislative committee on chiropractic, whose hearings were reported in this JOURNAL, (January 15, p 85, and February 15, p 201), is printed on page 375 of this issue. It is entirely colorless and will probably not be satisfactory to either the chiropractors or the medical profession. However, from the point of view of the doctor, the report has one ele-

ment of satisfaction, in that the cultists failed to secure a formal recognition. The cultists had scored a point last spring when they received the recognition of an investigation by a legislative committee. They now have neither the approval of a representative group of legislators, nor the glory of martyrdom which would have followed a condemnatory report.

## COUNTY DEPARTMENTS OF HEALTH

Governor Smith's hearing on the establishment of County Departments of Health, reported on page 314 of the March 15 issue of this JOURNAL, has aroused interest in the movement, although there are misapprehensions regarding the proposed plan. The decision regarding the establishment of the County Departments rests with boards of supervisors, and they are influenced by what they consider to be objectional features quite as much as by those which are desirable. Misapprehensions are as potent as proven facts, and will prevail when future conditions which cannot be guaranteed are considered.

Most members of the boards of supervisors are also presidents of the boards of health of townships, and know a considerable amount about public health work. They realize the incompleteness of the work of local health boards and health officers, and the geographic limitations of their jurisdictions, as, for example, in the promotion of pure milk supplies, and the control of travel by persons infected with contagious diseases. They also frequently express the wish that the State should assume the control of conditions in which no immediate menace to health is evident. They agree that the county can accomplish many public health objects which towns and villages cannot attain. They believe in a County Health Department as an abstract proposition. Why do they not adopt it for their own counties? The answer is the prevalence of three misapprehensions.

First, the members of boards of supervisors do not have a clear conception of what a County Department of Health should do, and no official designs have been announced. However Dr. Paul B. Brooks, Deputy Commissioner of Health, devised an unofficial outline which was published on page 985 of the December 1st, 1926, issue of this JOURNAL. Dr. Brooks outlined eight general duties as follows:

- 1 Inspection of dairies
- 2 Inspection of camps, boarding houses, and maternity houses
- 3 Control of nuisances affecting more than one local district
- 4 Control of contagious diseases involving more than one municipality
- 5 Scientific epidemiological work
- 6 Promotion of county-wide projects, such as laboratories and diphtheria immunizations
- 7 Assistance to local health officers
- 8 Conducting a continuous educational campaign

This is a definite program, and one which members of local boards of health can understand. If it were formally announced, the boards of supervisors would have something

tangible to consider, and would know what they are asked to adopt.

The second misapprehension is that regarding the relation of the present local boards of health to the County Health Department. Members of boards of supervisors seem to have the impression that local health boards will be abolished and all forms of health work will be done by the county. Possibly this impression is strengthened by the proposal of Commissioner Nicoll, made at the Governor's hearing, that the boards of supervisors be permitted to abolish a local board of health. Two facts are in evidence that the abolition of local health units is not contemplated.

(a) All the published plans retain the boards of health and health officers in the towns and villages, and make the County Department complementary to local units.

(b) No County Department plan has considered the control of local conditions which affect one municipality only, but each town and village is responsible for its own standards of civic housekeeping.

The third misapprehension is that regarding the cost of an efficient County Department of Health. Commissioner Nicoll outlined an efficient county unit to cost approximately \$20,000 annually, but the impression made by his figures was overshadowed by the fact that the Cattaraugus County unit is costing \$100,000, or five times the estimate of Dr. Nicoll. The supervisors argue that since the Cattaraugus demonstration has been widely advertised as a model in form and efficiency, therefore Dr. Nicoll's estimate is merely a preliminary estimate which will be raised in a very few years to the budget of Cattaraugus County.

The answer to the argument of expense is that the Trustees of the Milbank Fund, which has financed a large proportion of the expenses of the demonstration, have made intensive studies, and have carried on wide experiments which could not be supported with public funds. The leaders in the Cattaraugus County unit do not expect that every phase of its public health work will be continued, but when the Milbank Fund withdraws its support, the budget will approach that proposed by Dr. Nicoll.

County Health Departments are essential in order to bring rural public health work up to city standards. Their attainment will depend largely on two conditions: (1) the development and statement of a definite economical plan of organization and activities, and (2) an active campaign of publicity and education of both the medical profession and the people.

These two activities may properly be developed by the Public Relations Committee of the Medical Society of the State of New York.

## THE FIELD OF ORGANIZED MEDICINE

Organized medicine means societies whose members are physicians and whose purposes are directly connected with the practice of medicine in some form

The medical profession means physicians collectively in distinction from physicians as individuals. The term is vague and impersonal, and when a physician expresses his views on a subject, the people are likely to accept his dictum as that of the majority of other physicians. Doctors have, therefore, banded themselves into societies in which medical problems are discussed and standards of action are adopted and promulgated. The medical society is, therefore, the incarnation of the medical profession. It is the tangible body in which the soul of scientific medicine resides. The medical society in modern health work is as essential as individual family doctors.

Medical societies have characteristics as varied as those of individual doctors, but the standard organization in which all physicians may be active is that comprising the county, the state and the nation. The county medical society is the accepted unit which represents the medical profession in general matters pertaining to health, while special societies, such as the Society of Medical Jurisprudence, represents the physicians who are specialists.

Organized medicine has a three-fold field of service

- 1 To physicians themselves
- 2 To medical science
- 3 To the people whom the doctors serve

The appeal of a medical society to physicians is either individualistic or social. The immediate, tangible benefits to be had from a county society are scarcely more than malpractice defense and a subscription to the State Journal of Medicine. These benefits are wholly inadequate to attract physicians of an intensely individualistic nature into a county society. To one who lacks the social temperament, the medical society can make no appeal, although he may be a skilled physician, a conscientious student, and a successful practitioner. But the majority of doctors are social and delight in their associations with one another. They desire to assist and to be assisted when dangers threaten, they wish to receive and impart medical knowledge, and to inspire and be inspired in the practice of the healing art. They are attracted to one another by a strong fraternalism in the possession of living secrets which are mysteries to the uninitiated. The greatest personal satisfaction which a doctor gets from his medical society is that of association with kindred spirits, and of giving as well as receiving.

The second field of service of a medical so-

ciety is that of scientific medicine, which may be either individualistic or social. Every doctor wishes to know what to do when he is confronted with a specific condition. He was formerly satisfied to memorize a list of names of diseases together with the drug or procedure which was good for each. This was individualistic medical science. But the modern doctor is animated with the more social desire to promote scientific medicine. Abstract ideas are among the strongest motives that actuate men. Scientific medicine is the ideal which has always actuated physicians, and has led them to found medical societies. To be recognized by one's professional brethren as the discoverer of a new fact in medicine gives a thrill which compensates a doctor for weary hours of toil, and permits him the further satisfaction of donating it freely to his colleagues.

The county medical society is a potent agent in the promotion of scientific medicine. It is the forum where a new medical idea receives its final test of whether or not it can be put to practical use by the great majority of physicians.

Scientific medicine owes much to the rank and file of family doctors. They are the field workers to whom first come the patients who afterward constitute cases reported by renowned specialists, and it is family physicians who test new discoveries under every conceivable condition of actual practice. Every member of a county medical society shares in the satisfaction of promoting the cause of scientific medicine.

The third field for organized medicine is the people whom doctors serve. This field, too, may be individualistic or social. It is individualistic when medical service is rendered only to those who seek the doctor, bearing gifts. But physicians now recognize the duty of putting medical service within reach of every person. How to do it will never be solved by doctors acting individually, its solution must come through medical societies.

At the present time the most acute problem before the Medical Society of the State of New York is that of giving the best possible medical service to every person. Its solution involves consultations and agreements with non-medical organizations, and the adoption of new methods of procedure adapted to modern conditions. The problem is not scientific, for the knowledge is already available which, if applied, would cut human sickness and suffering in half. The problem is social and economic, and agencies along these lines must co-operate with medical societies in devising means by which physicians can apply their ministrations with the maximum benefit.

## SPINAL ANESTHESIA IN THE REDUCTION OF FRACTURES

The reduction of fractures with malposition of the broken ends often requires some form of anesthesia, either local, or spinal, or general. The two-fold object of the anesthesia is to prevent pain, and to secure muscular relaxation. Sensory anesthesia is readily attained, but it is not sufficient if the muscles are contracted and tense.

Local anesthesia is often effective in preventing pains, and sometimes it breaks the reflex arc which produces muscular contraction.

General anesthesia removes the influence of the brain upon the muscles, but a dangerously

large amount of ether may be required to abolish the spinal reflexes completely.

Spinal anesthesia is theoretically ideal, especially for overriding fractures of the leg, for it prevents the passage of all nervous influences. It paralyzes all the nerves, sensory, motor and sympathetic. The anesthetic takes effect at once, and the relaxation which it produces is complete and offers no resistance to the surgeon as he adjusts the bones. From the point of view of "setting" a bone, spinal anesthesia is satisfactory. Its use will depend on the condition of the patient, and the skill and preference of the operator.

---

## STRICTURE OF THE URETER

When ovariectomy was introduced, it was the favorite operation for the relief of pain in the lower abdomen, and then a generation ago appendectomy took its place. Within the last five or ten years it has become known that many pains which simulate those of diseases of the ovary and appendix are in reality due to stricture of a ureter.

Ureteral stricture is far more common than is usually supposed, and it is probably overlooked more frequently than it is diagnosed.

Practitioners of medicine are likely to have appendicitis always in mind and to diagnose

the condition when it exists. It has also happened that an operation discloses a healthy appendix and that later a strictured ureter is found to be the cause of the pain. The time has come when the ureter is to be borne in mind equally with the appendix as a cause of abdominal trouble. The cystoscope and the ureteral catheter are now available in the hands of nearly every surgical consultant, and there is small excuse for failure to use them in doubtful cases.

Ureteral stricture is discussed in the leading article in this JOURNAL.

---

## LOOKING BACKWARD

### THIS JOURNAL TWENTY-FIVE YEARS AGO

*Surgery of the Heart* The surgery of the heart seems to be in about the same state of progress that it was in 1902, if one may judge by the following editorial in the Journal for April, 1902.

"It is not many years since the medical world was startled by the report of a surgeon of repute that he had invaded the region of the heart, entered the pericardium and actually stitched up a deep wound in the walls of the heart itself. His example has been followed since by others and such work is no longer regarded as the work of a reckless enthusiast, on the contrary, the tendency is to extend the sphere of operations along these lines.

"Sir Lauder Brunton, of St Bartholomew's Hospital, London, a medical man, has conceived the idea of operating upon the living subject for the relief of the contracted mitral orifice. He has not yet had the temerity to operate upon the pulsating human heart, but has performed a se-

ries of experiments on the lower animals, thereby endeavoring to justify the procedure, at least experimentally.

"For the division of the valves of the heart a knife, like a tenotomy knife, is used with a cutting edge of about one half-inch. The valve is divided with comparative ease through the thickened edge, thus elongating the natural opening.

"Dr Brunton thinks that the good results that have been obtained in the treatment of wounds of the heart justifies one in hoping that ere long good results may be obtained in operating upon mitral stenosis.

"It seems rather strange that such a bold suggestion should come from a physician rather than a surgeon. But the risks and the dangers attending such an operation would, doubtless, have to be looked in the face for many a day before a surgeon will be found bold enough to put it into execution."

# MEDICAL PROGRESS

**Double Tachycardia, Auricular and Ventricular, Due to Digitalis**—Tasker Howard, writing in the *American Journal of the Medical Sciences*, February, 1927, clxxiii, 2, says that, although the popularity of large doses of digitalis has greatly enhanced the value of this drug, the danger of overdosage is a very real one. The occurrence of an A-V block as a result of digitalis has long been well known. A number of authors have pointed out the danger of mistaking the rapid, regular, cardiac action of ventricular tachycardia due to digitalis for an auricular flutter, for which more digitalis would be indicated. Howard reports the fatal case of a woman, eight months pregnant, whose pulse was 168 and quite regular except for recurring waves of somewhat more rapid action which appeared to be of sinus origin. The electrocardiogram showed a regular series of P waves recurring at the rate of 195. This represents an auricular tachycardia originating in an ectopic focus in the auricle. There was complete A-V block and a perfectly regular series of ventricular beats occurring at the rate of 160 and showing a normal "supraventricular" form. The ventricular tachycardia evidently originated in a focus lying between the A-V node and the bifurcation of the bundle. This combination of auricular tachycardia, A-V dissociation, and ventricular tachycardia seems to be a characteristic digitalis effect and should arouse the suspicion of overdosage with the drug. The occurrence of a rapid, regular pulse following the administration of drugs of the digitalis class should be studied by the electrocardiograph before one proceeds further with their administration.

**High Blood Pressure in the Young**—O. Moog and K. Voit state that they have recently had under observation a relatively large number of young folk with hypertension. Within the space of 15 months they had observed 16 subjects between the ages of 16 and 28 with blood pressures ranging from 140 to 215. Of this number 10 showed anomalies of constitution. There was no reason for thinking in this connection of presenility, but instead of this an hereditary or congenital factor could be invoked. There is supposed to be an exaggerated response to adrenalin in young hypertensives, and of nine subjects tested by the authors in this respect but two showed a lowered response. Cardiac hypertrophy is very rarely recognized clinically in this group and but two of ten tested showed increase in the basal metabolism. Of several patients whose cases are given in detail the youngest was a boy of 16 whose systolic pressure varied con-

siderably, sometimes reaching 170. Examination showed nothing abnormal from the clinical angle although the basal metabolism was elevated 20 per cent. There was no evidence of thyrotoxicosis although the pulse, even at rest, did not go below 100. No test with adrenalin is mentioned. Any complaints on the part of the patient seem to have been purely subjective. The systolic pressure was not uniformly high and at times it was normal for the age period. The patient was not treated. In some of the other histories drugs were given solely in the interest of diagnosis, to determine what would bring down the pressure or aggravate it. Adrenalin usually produces a prompt increase in an ordinary blood pressure while caffeine may lower it. Lumbar puncture sometimes lowers the blood pressure. In certain cases caffeine raises the pressure while adrenalin lowers it at first, this change being followed later by an increase.—*Muenchener medizinische Wochenschrift*, January 7, 1927.

**Leucemia or Sarcoma of the Blood**.—Sydney M. Cone, writing in the *Archives of Surgery*, February, 1927, xiv, 2, emphasizes the resemblance of myeloid leucemia to sarcoma and reports two cases which supply additional evidence that the leucemias may be regarded as sarcoma developing in a fluid medium. In both cases necropsy revealed chronic myeloid leucemia. In these cases the myelocytes were seen keeping their place in blood vessels in an orderly way, but here and there—in the brain, liver, intestine, spleen, serous membranes, and bone—there was a break and invasion occurred as in sarcoma elsewhere. The bone demonstrated masses of cells of a specific kind in the marrow. Here there were masses of large myelocytes (15 to 20 mm) with lobulated nuclei and a few with single nuclei in which nuclear division (carvogenesis) was evident. Vessel destruction and absence of other elements of the marrow were evident. There were no other cells (osteoblasts, endosteal or connective tissue cells) lining the bone, except in the temporal bone in one case in which some of the spaces were lined with a vascular myxomatous tissue. Bone absorption by direct action of the tumor cells was noted, and there was likewise proliferation of the bone cells as seen in other sarcomas of bone. It appears that any of the mesenchymal cells of bone and marrow may take part in the formation of leucemic cells. In explaining the origin of sarcoma from marrow, bone, reticular, endothelial, or other mesenchymal cells, Cone says that the cell stimulated to the point of embryonal activity and appearance (in sarcoma and cancer) remains at this stage of its

life history and continues to multiply indefinitely. It is easily conceivable that this process may be stimulated or actually produced by infections. There is evidence showing that various infections are associated with the leucemias. In several hundred necropsies Cone has seen the myelocytes multiplying in infections and in poisoning by wood-alcohol, carbon-monoxide, phosphorus, and cantharides, and he has also frequently noted great increase in the normoblasts and bone-cell multiplication. In leucemia, as in sarcoma, the cell does not complete its development. It acts like a malignant growth clinically and its morbid anatomy and histological pathology indicate that it is of a sarcomatous nature.

**Diagnosis and Treatment of Ankle Sprains**—V W Murray Wright takes exception to the indiscriminate strapping of ankle sprains without any regard as to what ligaments have been injured. The sprain is more often the result of inversion than of eversion of the foot, the external and anterior ligaments being, in consequence, most often involved. The ankle should be observed and any abnormality of position, size, or appearance noted, and whether effusion is below the malleolus or anteriorly or posteriorly at the weakest points. The patient is asked to place his finger on the spot that hurts most. Invariably the finger falls directly on the injured ligament. The area pointed to is then tested by inversion, eversion, extension, and flexion to learn if more than one ligament is involved. The foot should be so placed as to overcorrect the injured ligament, if the foot is then in the position of greatest comfort, the diagnosis is correct, and the foot may safely be immobilized in this position. Bandages cannot maintain immobilization. Adhesive plaster serves the purpose much better for at least 80 per cent of the cases. The adhesive strips used by the author are 24 inches long and 1½ inches wide. Each succeeding strip overlaps the other one-half its width, and a short strip is placed at right angles over the finished ends. The method of strapping must be suited to each case individually. The straps are left in place for at least five days, if there has been little swelling and the foot has not been used too much they may be left on a week before new ones are applied. Moderately severe sprains should be strapped for a week or two, then an elastic ankle support should be worn for two weeks. Severe sprains and sprain fractures should be immobilized by moulded plaster splints. If seen within four to six hours after the injury has occurred, cold applications will check the amount of effusion. After this period heat will promote absorption of the exudate and relieve pain. The removal of weight-bearing for at least twenty-four hours is the first and best remedy. In severe cases crutches should be used until the ligaments

are well under way to repair—*Therapeutic Gazette*, January 15, 1927, vol. 1, 1

**The Bacterium Causing Rheumatic Fever and the Therapeutic Action of Its Specific Antiserum**—James Craig Small (*American Journal of the Medical Sciences*, Jan 7, 1927, vol. clxxii, p. 1) describes a streptococcus which was isolated first on April 5, 1926, from a blood culture of a patient with acute rheumatic fever, and later from the throats of other patients with rheumatic fever. This microorganism is capable of producing characteristic arthritic and cardiac pathology, including Aschoff nodules in rabbits. The organism is a spherical Gram positive coccus which in fluid medium yields diffuse growth and shows short chain formations. It is readily stained by the ordinary aniline dyes. It is nonmotile, aerobic, and facultatively anaerobic. It is of rather constant, uniform size, varying from 0.7 to 1.2  $\mu$  in diameter. The optimum temperature for growth is 37° C, though growth at lower temperatures occurs. It shows a characteristic growth on blood agar. This organism has been designated as the *Streptococcus cardioarthritidis*. With this species of streptococcus a therapeutic antitoxic serum has been prepared, first in the rabbit and then in the horse. The administration of this serum in proper dosage in nine cases of rheumatic fever has been followed in a very striking manner by improvement of the outstanding clinical symptoms—pain, tenderness, swelling, and stiffness of the joints. Vaccines of the organism have been used with benefit in a certain number of patients with subacute cardioarthritis or with chronic arthritis. They have failed to produce benefit in other cases of these conditions. On the basis of his observations Small regards this microorganism as the cause of rheumatic fever.

**Transient Hepatic Acholia**—Max Einhorn calls attention to a type of transient acholia which he believes is not so rare as it appears to be. He reports the case of a man who attended a banquet, ate sparingly, but afterward drank five or six glasses of ice-water. During the night he suffered an attack of watery diarrhea, without a trace of bile, fecal odor, or disagreeable sensations in the abdomen. This type of diarrhea indicates a disturbance of liver function. The watery stools with unchanged food in them ejected every half hour, in combination with partially suppressed urinary function pointed to rapid passage of the contents with failure of digestion and absorption. The hepatic insufficiency probably caused this rapid unloading of the alimentary tract as a safety measure. For this reason the condition could be designated "transient hepatic acholia." The only discoverable reason for the disturbance was the drinking

of large quantities of ice-water Just as the liver can be brought to a higher temperature and increased activity by filling the stomach with hot water, it is to be expected that the ingestion of very cold water will lower the heat of the liver and lessen its activity The diarrhea also served as a protective process by freeing the alimentary canal of all work and thus relieving the liver of its duty as supervisor and giving it the needed rest The hypocholia in this case lasted three days when the liver apparently resumed its normal function With attention directed toward this liver dysfunction, Einhorn thinks it will probably be met with more frequently—*Southern Medical Journal*, January, 1927, vol xx, p 1

**Anuria Without Edema Decapsulation—**E Glass, a surgeon of Hamburg, reports the case of a woman of 60 who consulted him for joint pains and chanced to state that she was not passing any water The catheter showed an empty bladder She was placed under observation and shortly after, the anuria persisting, developed a chill followed by rise of temperature Abdominal palpation showed a tumor in the right renal region Blood pressure 135 Professor Korach in consultation hesitated to make a diagnosis of nephritis The temperature was probably due to a left-sided bronchitis of the lower lobe or a right pyonephrosis Diuretics failed to start urine and the catheter failed to bring any away On the tenth day of anuria an exploratory incision was made and the right kidney was found to be nearly normal in size, the slightly adherent capsule was rapidly removed and a retention catheter inserted Defervescence followed and the urine began to collect The pulmonary lesion was now recognized as an apyretic bronchopneumonia The urinary flow was not maintained and coma developed, relieved for the time by venesection The patient succumbed to cardiac failure and although total autopsy could not be obtained the operation wound was opened and bits of both kidneys and the liver were removed The microscope showed severe subacute extracapillary glomerulonephritis of both kidneys The early assumption of reflex anuria of the left kidney was an error The decapsulation did neither harm nor good The case shows that renal pathology is still a dark subject and likewise the unsatisfaction of treating a case of such interest in a private house where the records—blood pressures for example—must often be incomplete—*Deutsche medizinische Wochenschrift*, December 24, 1926

**Spastic Ileus—**F Colmers mentions the original cases reported in 1897 by Heidenhain The affection may be acute, chronic, or postoperative Diagnosis before operation is well nigh impossible Merely to suspect it if the constitutional symptoms are favorable is treacherous, for

we may delay operating until intervention is too late The spastic condition is recognized at operation as one or more annular stenoses of the small intestine, or an entire segment of the small or large bowel may be contracted down to the thickness of a finger In some cases operation alone seems sufficient to relax them, but operators have often seen fresh ones develop in the midst of the operation Spastic ileus is nothing but one of a group of myospasms of the alimentary canal such as may be excited by any local irritant within the canal or by the act of laparotomy with the mauling about of the intestines by the operator The phenomenon has also been seen in lead poisoning, influenza, hysteria, etc The occurrence of these spasms however is not the same as spastic ileus, for the latter condition must be attained very rarely while myospasm of the intestine are doubtless extremely common A special factor is necessary for myospasms to become ileus and this must be some liability of the autonomous nervous system Spastic ileus is a surgical affection and must be treated by laparotomy which is largely an exploratory procedure, and if much meteorism is present an enterostomy should be done Medical measures are useful for prophylaxis and atropine may be tried before laparotomy if the case seems subacute or chronic, but not in the acute form The author is strongly opposed to the custom of giving eserine after operations to secure peristalsis because of the risk of setting up postoperative spastic ileus Instead he would make use of atropine, chloral, etc—*Muenchener medizinische Wochenschrift*, December 24, 1926

**The Danger of Infection About the Face—**J William Hinton, writing in the *Annals of Surgery* for January, 1927, vol lxxxv, 1, states that the complications which small furuncles around the upper lip and nares may produce are not generally recognized In active hospital services one sees one or two deaths yearly from maltreated face infections These fatalities do not result from medical procrastination, but from overzealous surgical intervention Owing to its patency the facial vein favors septic absorption, and therefore any phlegmonous inflammation of the face following a poisoned wound is liable to set up thrombosis in the facial vein, and detached portions of the clot may give rise to purulent foci in other parts of the body On account of its communications with the cerebral sinuses, these thrombi are likely to extend upward into them and so induce a fatal issue Furuncles about the danger zone of the face should not be traumatized by squeezing or small incisions It is best to treat all face infections conservatively Heat is best used in the form of flaxseed poultices, which are preferable to wet dressings If the patient has chemosis, hot boric compresses may be applied to the eyes With conservative treat-

ment the infection will usually localize, and frequently will spontaneously perforate through the skin or mucous membrane and the slough will be discharged. If the infection does not localize, an incision with a very sharp scalpel should be made, under general anesthesia, without traumatizing the area. The wound should not be packed with gauze, but a rubber drain should be inserted to hold the edges apart, and hot poultices should be applied.

**The Carbon Monoxide Menace and the Cancer Problem**—Georgine Duden (*Canadian Medical Association Journal*, January, 1927, vol. vii, p. 1) asserts that the ubiquity of carbon monoxide in modern life can hardly be overestimated. The exhaust gas from an automobile contains from 4 to 9 per cent, or 400 to 900 parts of carbon monoxide gas to 10,000 parts of air. A running car or truck puffs out one cubic foot of exhaust each minute. Other sources of the gas are domestic chimneys, factories, railways, steamers, defective gas fittings and heating apparatus. A concentration of 15 10,000 inhaled for a short time produces unconsciousness, which may prove fatal. A concentration of 6 10,000 causes fairly severe symptoms (headache, nausea, dizziness, weakness in the legs, and general lethargy), lasting from one to five days. Carbon monoxide creates a relative oxygen deficiency in the body. Loss of consciousness almost invariably follows a blood saturation of 40 per cent. Among the serious sequelæ of carbon monoxide poisoning have been noted activation of tuberculosis, pneumonia, alkalosis, diabetes, impairment of vision, gangrene of the extremities, and abortion in which carbon-monoxide could be demonstrated spectroscopically in the fetus. The physician who keeps the ubiquity of carbon monoxide in mind and inquires after gas fittings will reap a harvest of gratitude from a client in whom a low grade of poisoning is causing vague aches and miseries, whereas reference to "nerves" is likely to alienate the patient.

The relative oxygen deficit caused by the inhalation of a deadly gas is capable of upsetting the normal body chemistry, and the importance of chemistry in cancer research is generally recognized today, and attention has been called to the increase of cancer of the lungs, formerly consid-

ered a rare form of malignant disease. In this connection the author suggests that inhalation of irritating gases produced by automobiles, imperfect combustion of fuels, and industrial processes may be an important causal factor, although the difficulty is admitted of getting clear-cut evidence as to the effect of carbon monoxide on cell proliferation because of the complexity of the chemical processes involved in normal as well as in malignant growths.

**Intestinal Ulcers and Strictures in Pernicious Anemia**—I Zadek mentions the occasional discovery of these lesions at autopsy in cases of Biermer's anemia, and he raises the question of a casual connection between the blood state and disease of the intestine. In 1922 only eight of these cases were known to have been recorded. The author, however, has had four such cases in a total of 200 under observation, and gives them in detail with the following summary. There was no special type of lesion evident as the cases were respectively a stricture of the small intestine, a stricture of the colon, a large ulcer of the small intestine, and multiple ulcers in the same segment. The author, however, was able to show that, in three of the four cases at least, the lesions were tuberculous. The history of these cases showed a complete absence of any symptoms which could be ascribed to the lesions, and a diagnosis of the latter during life would have been impossible. One patient developed a diarrhea three months before death which may have been due to the presence of multiple ulcers of the small bowel. Could these lesions have had anything to do with the development of anemia? The age of the lesions or of some of them was not great enough to justify such a supposition. Neither was there anything to justify the much more plausible belief that the tubercle bacillus obtained a foothold in the intestine as a result of the greatly lowered resistance to infection. That intestinal strictures naturally favor the development and persistence of ordinary anemia may be true, but at present we can only reckon these lesions with various other gastroenteric alterations which have been seen to accompany pernicious anemia—*Muenchener medizinische Wochenschrift*, December 17, 1926.

By LLOYD PAUL STRYKER, Esq  
Counsel, Medical Society of the State of New York.

## PREVENTIVE METHODS AS APPLIED TO LITIGATION

The trend of scientific thought is in favor of preventive medicine. Thus from responsible quarters, we have the advocacy of periodic health examinations. We have witnessed the enormous strides in prophylaxis, and the measures which are invented and applied constantly for public sanitation. In the domain of private practice too, the personal physician regards it increasingly as his duty not only to heal his patient when he is sick, but to prevent him from becoming ill.

The theory of preventive medicine is based on common sense. It is the recognition of the fact that it is better to prevent mishap than to cope with it after it occurs. Upon this doctrine rest all of the modern safety appliances, and the laws requiring the use of these by railroads, in factories and wherever workmen are engaged in hazardous occupations. If this preventive theory is sound in medicine and industry, it is of equal validity in law. Many cases have come to the writer's attention that with proper foresight might have been prevented. Ofttimes, actions would not be brought were those who bring them certain that the doctor was able conclusively to establish the use of proper procedure and practice. Then too, as we have so frequently stated heretofore, where Dr. A is superseded by Dr. B, if the latter were to use a greater economy of criticism than is sometimes now indulged in, there would be less likelihood, as a result of the strictures made by Dr. B, that the patient would bring Dr. A into court as a defendant in a malpractice suit.

One of the means certainly by which a successful determination of a suit when brought would be made more likely is through the keeping and maintaining at all times of proper records. Frequently, the whole case will turn upon the question of what was the patient's temperature at a given day or hour. Very often, the writer has seen cases where the doctor was unable to establish this vital point because he either did not take or keep a record of the fact. The importance of records can not be overemphasized. This applies, not only in hospitals, but in private offices. A doctor should make a contemporaneous memorandum of each case he treats which should contain the statement of his examination, diagnosis, treatment and prescription, as well as the history of the case when it comes to him. All

of the vital points, such as temperature, pulse, respiration, pathological reports, etc., should be accurately kept and painstakingly preserved. There is tremendous probative force in a contemporaneous memorandum. Sometimes the possession of these things has been the means of winning cases that otherwise would have been difficult indeed to win.

Then there is the question of the transactions between the doctor and the patient. Take, for example, where Dr. A decides to go on a vacation and puts Dr. B in charge. In such a case, it is always necessary to give the patient notice of the intended absence and arrange for another physician to take one's place during his absence. Then too, oftentimes a question will arise as to the instructions given by a physician to his patient. It is the physician's duty to give the proper instructions. To fail in this or to give no instructions at all, if such a failure can be traced to a bad result, may render the physician liable. Where a doctor advises an operation or a certain course of treatment which the patient does not wish to follow, it would be the part of wisdom to give this advice in writing. It would then be impossible later for the patient to assert that such instructions never had been given. If proper instructions are given, and the patient fails or refuses to follow them, the doctor is not liable for such results as may ensue because of this.

Recently there was brought to the writer's attention a case involving roentgenology, wherein it was a vital point to establish that a certain X-ray picture which had been taken before the doctor had begun his therapeutic work was in fact the picture of the organ of the patient. This was disputed, and the physician was unable to establish it through his records. X-ray pictures should be carefully indexed and cross-indexed against the patient's name, and should be carefully preserved for at least five years after their taking, and for a longer period in the cases of X-rays of children. If difficulty is anticipated, it would be well to have the patient sign his name upon the X-ray picture, thereby identifying the same once and for all as his.

Various systems of record-keeping have been devised, and are in use. Doubtless some are better than others, but the kind that will assist the doctor is that which will show the necessary facts of the history of the case.

## FRACTURE OF CLAVICLE AND CONDYLE OF THE HUMERUS— IMPAIRMENT OF FLEXION

An action was brought on behalf of an infant, a boy about nine years of age, charging negligence upon the part of the defendant physician in the treatment of a fracture. An action was also brought by the mother to recover for the expenses incurred in the treatment of the boy and for loss of the boy's services.

It was stated that on the 22nd day of April the boy had fallen in an areaway sustaining a severe injury to his right arm, that on that day the defendant as a physician was engaged to attend and treat the injury, that after examination the defendant diagnosed the injuries and stated that the ligaments, muscles and tendons of the boy's right arm were strained and torn, but that the arm was not broken nor any bones thereof, and he requested X-rays to be taken of the injured arm. In compliance with the request the mother had X-rays taken which she submitted to the defendant physician on the following day. After examination of the X-rays the defendant physician confirmed the previous diagnosis stating that there was no fracture of any of the bones of the arm and he continued to treat the boy for the strained and torn ligaments, muscles and tendons. That on June 22nd the mother caused the patient to be examined by another physician and at that time exhibited to the other physician the X-rays which had been taken on the day of the injury and which had been exhibited to the defendant physician. That this physician upon examination of the patient and the X-rays informed the patient's mother that a piece of the external condyle of the humerus was broken off, out of position, forward and ankylosed, thus interfering with flexion of the joint, and that in order to unite it in proper position it would be necessary to operate and remove this piece of bone, that such an operation was subsequently performed. It was charged that while the defendant was attending the plaintiff he failed to correctly diagnose the injuries and failed to give to the patient the correct and proper treatment for the injuries from which he was suffering. That he was negligent and careless and failed to exercise the proper care and skill in his treatment of the patient, and that by reason of such negligence the patient's arm remained in a broken condition until operated upon by another physician. That the patient was confined to his house and a hospital for some period of time and that his arm by reason of the delay in the diagnosis and the reduction of the fracture will be permanently injured. Damages in the sum of \$25,000 were asked in behalf of the infant patient and \$5,000 in behalf of the mother.

On April 22nd the defendant physician was called by another physician to examine and attend the infant plaintiff. At about 12 30 P. M. of April 22nd, the defendant physician, accompanied by the physician who had called him, examined the injured arm and after such examination made a diagnosis of probable fracture or dislocation of the elbow. The arm at this time was helpless and the elbow was swollen and extremely tender. The arm was held in a position of flexion at 90°. It was impossible to determine exactly the nature of the injury, but the presumption was that there was a fracture. The mother was advised that X-rays should immediately be taken and further advised of the probability of either a fracture or dislocation or both. The mother, a chiropractor, stated that she would have the X-rays taken by a friend of hers another chiropractor. After examination the boy's arm was put in a temporary fixation bandage so as to permit the boy being transported and the X-rays to be taken. At about 5 o'clock of the afternoon of April 22nd the X-ray films were examined by the defendant physician. The films were not very clear, but were sufficiently clear so as to show two conditions, a fracture of the clavicle in its middle third and a comminuted fracture of the humerus extending into the elbow joint with forward displacements of the condyles.

The physician states that it is customary in children up to the age of fifteen years, where there has been a bone injury, because of the difficulty of interpretation due to the lack of bone ossification, to take X-rays of the uninjured side and thereby be able to make a comparison of the X-ray films of the injured and the uninjured side. This was not done in this case, there being X-ray films of only the injured arm. The defendant physician, however, felt that the X-ray films were sufficiently definite so as to enable him to determine the proper method of treatment.

After examination of the X-rays the mother of the patient was advised that on the following morning an anaesthesia would be administered and a reduction made of the fractured humerus and clavicle. At about 10 A. M. of April 23rd, at the patient's home an anaesthesia was administered by a physician and the defendant then manipulated the fractured bones placing them apposition and the arm in a position of hyperflexion, the elbow and arm being fixed against the chest wall so as to immobilize the fractured clavicle. A starch bandage was applied. At this time and frequently thereafter the mother was told by the defendant physician that fractures of the elbow in child-

ren have a long and stormy course before function is restored and the elbow is back to normal. The physician saw the boy on the second and third days and at that time told the mother that in about ten days he would remove the bandage and begin movement of the elbow. On the ninth day after the injury the bandage was slit down and passive motion and massage of the elbow was begun. During the period between the application of the cast and the time when the same was opened up and passive motion begun, the patient was visited several times by the defendant and examinations made to make sure that the hand was not turned or that there was no nerve involvement. After the slitting of the cast and the giving of the passive motion and massage the cast was reapplied, brought together and held in place by adhesive strips. Two days later the same treatment was rendered and then gradually at more frequent intervals until at the end of about three weeks when the cast was entirely removed, passive motion was continued, extension greatly increased until the boy was able to extend the arm about  $135^{\circ}$  at the elbow joint. In spite of all efforts on the part of the defendant physician a greater extension than  $135^{\circ}$  could not be procured. The injured parts were bathed in hot water by the mother who also massaged and gave passive motion to the same.

Upon the advice of the defendant physician, during the first week in June the mother took the child to a well recognized physio-therapeutic physician. This physician after examination gave an unqualified favorable prognosis as to the restoration of function and advised the application of diathermic treatment. After six or seven treatments had been administered by the physio-therapist the boy was again brought back by the mother to the defendant physician, the mother being dissatisfied with the treatment of the physio-therapist claiming that she saw no improvement in the boy's arm and complaining that the boy was not receiving personal attention from the physio-therapist. The defendant physician then recommended another physio-therapist who, after examination gave a favorable prognosis and the boy continued under the care of this physician for about a month. After the boy had been placed in the care of this physician the defendant physician advised the mother that his treatment of the boy was ended and that further treatment would be given by the physio-therapist. Shortly thereafter the defendant rendered a reasonable bill to the mother for the services that he had rendered. The mother stated that she was unable to pay the bill because of financial stringency though she admitted the bill was reasonable and in the middle of July paid half of the bill. Nothing fur-

ther was heard of the patient until some weeks later when the defendant physician saw the boy playing in the street and upon speaking to the boy, he told the physician that he was going to a hospital where they were going to stretch the arm.

The defendant physician thereupon by telephone inquired of the physio-therapist who stated that the boy had been operated upon by a surgeon. Nothing further was heard from the patient by the defendant physician until the following December when he communicated with the surgeon who had subsequently operated upon the boy. The surgeon after examination had made a diagnosis of excessive callus formation at the elbow and had operated to remove the callus formation. The operation was performed on August 22nd. According to the records of the surgeon the arm in December was in about the same condition as it was in the previous August.

The first physio-therapist to whom the boy was brought for treatment stated that he first saw the boy about June 15th, that after examination he gave him diathermia, massage and manipulation of the muscles of the arm and shoulder. That the treatment was repeated on June 25th, 27th and 29th. That after this last treatment the boy's mother notified this physician that she would not bring him back for further treatment. This physician advised the mother that he could improve the boy's arm if she would bring him back, but she refused to do so.

The second physio-therapeutic physician saw the boy on June 29th. He stated that he found a healed fracture of the elbow. He likewise gave diathermia, manipulation and baking. His treatment was repeated twenty-six times, the last treatment being given on August 12th. He suggested to the mother that the boy be given a series of treatments extending over a period of three months. The mother, however, refused to bring the boy back to this physician. At the time the last treatment was rendered to the boy he found that the motion of the boy's arm had improved and that he did not seem to have as much pain as he had when first brought to this physician.

The physician who was first called at the time of the boy's injury and who had called the defendant in, stated that at that time a diagnosis was made of a fracture of the elbow and that the boy's mother was then advised of the fractured condition of the elbow and also advised to have X-rays taken so as to confirm the diagnosis.

The surgeon who operated upon the boy first saw him on August 14th. Examination by him showed a fracture of the supercondyle of the humerus, displacement forward, the upper end of the fragment was blocked. The

surgeon stated that he put the boy in the hospital and under an open operation removed a piece of bone which was blocking extension. After leaving the hospital the boy called at the surgeon's office for examination and treatment, his last call being in December, at which time the arm was found to be improved, no barking being done.

On April 13th, about a year after the injury a physical examination was made, at which time the examining physician found normal

flexion of the left elbow, extension possible up to  $170^{\circ}$ , there therefore, being a  $10^{\circ}$  limitation of motion. On the posterior aspect of the elbow there is a three inch healed scar. The strength of the elbow was found to be normal. The boy stated that the elbow or arm did not bother him in any way.

After a two-day trial the jury rendered a verdict in favor of the defendant in both actions.

---

### FAILURE TO DIAGNOSE APPENDICITIS RESULTING IN DEATH

On January 22nd the physician was called to attend a boy about nine years of age. Upon arrival at the boy's home he found him in bed with a temperature of  $99^{\circ}$ . The child complained of pain in the abdominal region. The entire abdomen upon palpation was somewhat tender but there was no marked rigidity of the muscles, particularly of the right rectus. The doctor prescribed quinine, the application of a mustard plaster on the abdomen and a lavative, and that the child remain in bed. On the following morning, at about 10 o'clock he again called at the child's home. He found the child up and about the house with no temperature and was told by the parents that the child was feeling better. He again examined the abdomen by palpation but found no rigidity of the muscles. During these visits the physician had in mind the possibility of appendicitis.

On January 24th at about 11 o'clock in the morning the child was again visited by the physician and upon examination found that the temperature had increased to about  $100^{\circ}$  and upon palpating the abdomen he found rigidity of the right rectus muscle and tenderness at McBurney's point. After this examination he made a diagnosis of probable appendicitis and advised the removal of the boy to the hospital and that he be placed under the care of a surgeon. At about 2 o'clock in the afternoon of that day, accompanied by the parents, the physician in his own automobile, took the child to a hospital and placed him under the care of a competent and capable surgeon. At the time the boy was taken to the hospital he was able to walk and was not complaining of any severe pain and upon arrival at the hospital sat in a chair in the sitting room. The defendant turned the care of the child over to the surgeon and this was the last time that the child was seen by the attending physician except that five or six days after the boy had been taken to the hospital while the

physician was in the hospital he saw the child in bed, inquired of his condition, but did not examine or treat him in any way.

On January 24th, the day the boy was delivered by the defendant physician to the hospital an appendectomy was performed by the surgeon. The appendix was found to be ruptured and gangrenous and a drain was placed in. The boy continued to improve and got along all right for about two weeks and seemed to be about ready to leave the hospital for his home when he suddenly ran a temperature. Between this time and the day of his death on March 1st, the surgeon performed several minor operations breaking up intestinal adhesions. The surgeon had found that intestinal adhesions caused an obstruction of the bowels with a resultant infection from the excrement, causing a general peritonitis, resulting in the death of the child on March 1st. The death certificate was signed by the house surgeon at the hospital and gave the cause of death as acute appendicitis, ruptured (operation) intestinal obstruction, contributory cause general peritonitis.

In an action brought against the physician to recover for the death of the boy it was claimed that the defendant physician was negligent and careless and had failed to diagnose the true condition and recognize the fact that the boy when first seen by the defendant was suffering from appendicitis. It was contended that if the defendant physician had possessed the knowledge and skill of a practicing physician in his locality he would have made a diagnosis of appendicitis upon the first visit, the boy could have then been operated upon and his life could have been saved.

When the action came on for trial the plaintiff was unable by competent evidence to sustain the theory of his complaint and at the close of the plaintiff's case the action against the physician was dismissed.

# NEWS NOTES

## THE ANNUAL MEETING

The arrangements for the annual meeting of the Medical Society of the State of New York on May 9-12, 1927, in Niagara Falls, are nearly completed. All the meeting places are on Jefferson Avenue within a radius of one block and are as follows:

*Niagara Hotel*, situated at the corner of Jefferson Avenue and First Street

*St Peter's Church*, on the northwest corner of Jefferson Avenue and Second Street

*Prospect House*, at the northeast corner of Jefferson Avenue and Second Street

*K of C Home*, on Jefferson Avenue at the head of Second Street opposite the Prospect House

Assignments of the Scientific Sections, Exhibits and Registration Places have been made as listed in the following table:

Section
House of Delegates
Medicine
Cancer Exhibits
Registration of Delegates
Dermatology
Neurology and Psychiatry
Pediatrics
Cancer Papers and Discussions
Surgery
Obstetrics
Public Health
Eye, Ear, Nose and Throat
Industrial Medicine
Registration of Members
Commercial Exhibits

be an address by William Ganson Rose of Cleveland, Ohio, nationally known advertising man and world traveller. Following the addresses there will be a short intermission when the room will be prepared for dancing. During intermission a Physicians' String Quartette under the leadership of Dr A. J. Ragone of Buffalo, will play in the lobby of The Niagara. During the banquet and for the dance the famous Isle's Blues Orchestra from Colgate University will play.

## ANNUAL MEETING

The Annual Meeting of the State Society will take place Wednesday evening, May 11th at 8 15 P M in the Chamber of Commerce Auditorium situated at 43 West Falls Street.

## LADIES' ENTERTAINMENT

Preparations have been made for the enter-

The principal meetings are as follows:

The House of Delegates meets Monday afternoon, May 9th, and Tuesday morning, May 10th.

A dinner of the members of the House of Delegates will be held at the Niagara Hotel on Monday evening, May 9th.

The Scientific Sections will begin at 2 30 P M May 10th, and continue during the morning and afternoon of May 11th.

The Cancer exhibits will be held May 12th, morning and afternoon.

Cancer papers and discussions, will be held May 12th at 2 00 P M.

The annual banquet and ball will be held on Tuesday evening, May 10th, beginning at 6 30 P M in the ballroom of the Niagara Hotel. The price is six dollars per person including the dance. In addition to the regular addresses by the convention chairman and president-elect, there will

tainment of the ladies, according to the following program:

Mrs William H Hodge, Hostess, 324 Buffalo Avenue, Niagara Falls.

**Tuesday, May 10th—2 30 P M** Bridge Tea at the Shredded Wheat Plant. Compliments of the Shredded Wheat Company. Just preceding the bridge tea the ladies will be conducted on a special tour of the factory.

**Wednesday, May 11th—Golf** at the Niagara Falls Country Club. Bridge Whist and Tea Prizes. The hour for this will be announced later. All ladies desiring to participate in the ladies' golf tournament should advise Mrs Hodge. Buses will be provided to transport the ladies from the hotel to the club.

**Thursday, May 12th—Mrs Hodge** has left this day for optional visits to the various plants,

such as the Niagara Falls Power Company, Wallpaper Plants, Cellucotton Plant, etc

The following entertainment has been prepared for the doctors Wednesday, P M—Golf tournament at Font Hill Golf Club, Font Hill, Ontario All doctors desiring to play in the tournament should make application for assignment to

Dr Carl G Leo-Wolf, Chairman, 108 Buffalo Avenue, Niagara Falls, N Y

### SCHOOL MEDICAL INSPECTORS

The State Medical Society meets this year at Niagara Falls on May 9th, 10th 11th, and 12th. The program will contain much that will be of great interest and assistance to the physicians of the State. We are particularly anxious to interest our school medical inspectors to attend the coming meeting of the Medical Society of the State of New York. I hope you are planning to be present.

An informal dinner and conference will be

held at 6 o'clock on May 11th at the Niagara Hotel. After the dinner several hours will be devoted to the presentation and discussion of practical problems. I hope you will reserve this time for an opportunity to meet with us. Please advise me either at Albany or at Niagara Falls of your intention to attend.

WILLIAM A HOWE,  
Chief Medical Inspection Bureau,  
State Department of Education

---

### HOTEL ACCOMMODATIONS AT THE A M A MEETING

Dr Olin West, Secretary of the American Medical Association, has sent out a plea that the delegates to the A M A shall make their reservations at once. Dr West has engaged a sufficient number of rooms for all the delegates, at the Mayflower Hotel, Washington, D C. Since the number of visitors will be very large, those who expect to come should make their reservations at an early date. Particularly Dr West requests the delegates to inform him whether or not they wish to make use of the rooms which he has engaged at the Mayflower Hotel.

Dr West writes

"If you have already secured accommodations at some other hotel, or if for other reasons you will not need a reservation at the Mayflower Hotel, please advise me at your earliest convenience at what hotel your reservation has been made or what your address in Washington will be. If, on the other hand, you have not made arrangements for accommodations in

Washington and desire to have one of the rooms we have tentatively reserved, please write at once to the Mayflower Hotel, Washington, D C, requesting the manager to assign for your use one of the rooms tentatively reserved for delegates, and stating what State association you will represent as delegate. Request the hotel also to advise you that your reservation has been made. If you do not expect to attend the Washington session, inform me accordingly so that we will not interfere with reservations for others who may wish to attend and may desire to be accommodated at the Mayflower Hotel.

"As soon as you have secured your reservation, please be kind enough to report that fact to this office. The Mayflower Hotel has made rates of \$5.00 to \$12.00 a day for single rooms and \$7.00 to \$15.00 a day for double rooms, European plan. I sincerely hope that it will be possible for you to attend the meeting in Washington."

---

### A COURSE IN MEDICAL BIBLIOLOGY

The Medical College of The Long Island College Hospital Brooklyn, has inaugurated a course in "Medical Literature and Bibliography." In a number of schools the importance of bibliographical knowledge has been stressed by individual teachers but so far as is known this is the first established course of this nature included in the curriculum of any medical school in the country. An attempt is being made to show the student the real value of literature which constitutes such an important part of the background of his work, and

to teach him how to use a library. The lectures will be given by Mr Charles Frankenberger, Librarian of the Medical Society of the County of Kings, whose wide knowledge of bibliography and of the relative values of medical literature can now be made available for the medical student as a part of his training. This course is also further evidence of the co-operation of the library officials of the Medical Society of the County of Kings, for they already have had created a special student membership with definite library privileges.

## ALLOTTMENT OF STATE MONEY FOR PUBLIC INSTITUTIONS

The bond issue of \$50,000,000 authorized by the State of New York, for additions to public institutions is allotted in four installments. The allowance of \$12,500,000 for 1927 is distributed as follows:

### *Binghamton State Hospital*

Employee accommodations—\$50,000

### *Buffalo State Hospital*

Nurses' Home for 50 nurses—\$160,000

### *Central Islip State Hospital*

Buildings to replace wooden structures in North Colony—\$600,000

### *Creedmoor State Hospital*

Bakery garage and superintendent's residence—\$230,000

### *Harlem Valley State Hospital*

Superintendent's residence and employee accommodations—\$160,000

### *Hudson River State Hospital*

Infirmery for 200 patients	\$550,000
Nurses' Home for 100	110,000
Staff House	50,000
Pavilion for Male T B cases	155,000

\$865,000

### *Kings Park State Hospital*

Building for Occupational and Visual Therapy (Veterans' Memorial Hospital)	\$250,000
Attendants' Home (Veterans' Memorial Hospital)	175,000

\$425,000

### *Matteawan State Hospital*

Superintendent's residence—\$50,000

### *Middletown State Hospital*

Reconstruction of pavilions Nos 1 and 2 and annexes Nos 1 and 2 and Talcott Hall—\$1,500,000

### *Napanoch*

Cell block for 200 and staff quarters—\$500,000

### *Newark State School*

Employee accommodations and staff quarters—\$210,000

### *Rochester*

Patient accommodations, employee accommodations and staff accommodations  
To complete the replacement of the Monroe Group—\$200,000

### *Rockland State Hospital*

To further development—\$4,000,000

### *Rome State School*

Staff accommodations—\$50,000

### *Syracuse State School*

Farm Colony at Fairmount—\$250,000

### *St. Lawrence State Hospital*

Employee accommodations and replacement of building for male tuberculars—\$350,000

### *Syracuse Psychiatric Institute and Hospital*

### *Wassaic State School*

To further development—\$2,000,000

### *Willard State Hospital*

Psychopathic reception service for 150—\$600,000

## 10,300,000 VACCINATIONS FOR SMALLPOX WITHOUT A SINGLE REPORTED CASE OF SYPHILIS

It has come to the attention of the undersigned that false statements are being circulated, that have caused some people to believe or fear that vaccination against smallpox may cause syphilis. Since the activities under our charge furnish direct evidence in refutation of this idea we have considered it our duty to issue a statement that syphilization as a result of vaccination does not occur.

Before the discovery of smallpox vaccine, the only protection against the dangers of smallpox was by inoculating a person intentionally with the disease and thereby producing, in general, a milder attack than that contracted when smallpox was caught in a natural manner. In this way the inoculation of syphilis along with smallpox, or even of syphilis instead of smallpox was possible. This possibility also existed when vaccination first supplanted smallpox inoculation, and was performed, as was smallpox inoculation, from the arm of one human subject to another. Cases of syphilis following inoculation or vaccination with human vaccine were, nevertheless, extremely rare. Syphilis, however, is a disease confined in nature to the human species alone, and as soon as the use of calf vaccine instead of

human vaccine became universal *the possibility of transferring syphilis by vaccination was entirely done away with*.

Since 1917 the United States Army has vaccinated approximately 4,700,000 members of its personnel, the United States Navy has vaccinated approximately 950,000 members of its personnel, and of these 5,650,000 persons, *not one* of them ever developed syphilis as a result of vaccination. In not one of them was there ever any suspicion of syphilis in connection with vaccination. During this same period, the United States Public Health Service has also vaccinated 2,918,748 persons in carrying out its quarantine, immigration and hospital work. While the Public Health Service has not always had the opportunity of following up these vaccinations, as is carefully done in the Army and Navy, no one has ever alleged that any particular individual vaccinated by the Public Health Service, has contracted syphilis as a result of vaccination.

During the past ten years more than 2,000,000 persons, including school children, have been vaccinated by State and local health authorities in cooperation with the United States Public Health Service, making a grand total of 10,568,748 vac-

cinations recorded by the Government medical services, and not one of the undersigned has ever received an allegation or a statement charging that any particular individual of this number has contracted syphilis as a result of vaccination. In fact, there has never been reported anywhere a case of syphilis attributable to vaccination following the use of bovine smallpox vaccine.

Smallpox vaccine is a standard medicinal product, the quality of which is prescribed by the United States Pharmacopœia and as such is subject to the provisions of the Pure Food and Drugs Law. Furthermore, smallpox vaccine, together with other vaccines and serums for human use, has been deemed of such importance by the Government that its production for sale within the jurisdiction of the United States has been under the special protection of an Act passed July 1, 1902, antedating even the Pure Food and Drugs Law. Under this law all establishments producing smallpox vaccine for interstate sale must be licensed by the Secretary of the Treasury upon the recommendation of the United States Public Health Service, and the production is con-

trolled by regulations drawn up by a board composed of the undersigned. These regulations provide for repeated inspections of the producing laboratories, for proper labeling, and for all safeguards which may be thrown about the making of such an important product. At present even the placing of the vaccine in the small tubes and the sealing of these tubes is required to be done in such a way that no hand, even though sterile, touches the vaccine. Repeated examinations of the product, for safety, are required.

This vaccine was used in the vaccination of the millions mentioned above and is exactly the same as that used by doctors in private practice in the vaccination of the general public throughout the United States.

(Signed) M. W. IRELAND,  
*Surgeon General, U. S. Army*  
E. R. STITT,  
*Surgeon General U. S. Navy*  
H. S. CUMMING,  
*Surgeon General, U. S. Public  
Health Service*

## REPORT OF THE JOINT LEGISLATIVE COMMITTEE ON CHIROPRACTIC

The purposes of this committee as set forth in the resolution of April 24, 1926, were

- 1 To investigate and inquire into the practice of chiropractic in the State of New York
- 2 To inquire into the nature and work of chiropractors within the State
- 3 To propose such legislation as such committee shall deem necessary for the regulation and control of the practice of chiropractic in the State of New York

Pursuant to said resolution, the following were appointed as members of the committee:

Senator John L. Karle  
Senator Henry G. Shackno  
Assemblyman Howard W. Allen  
Assemblyman Frank M. Smith  
Assemblyman John F. Reidy

The committee did not organize until December 22, 1926, at which time Senator John L. Karle was elected chairman of the committee.

During the month of December, 1926, only two meetings of the committee were held.

By reason of the expiration of the term of office of Senator John L. Karle as Senator, his membership upon the committee expired on December 31, 1926, whereupon on January 17, 1927, Senator Leonard R. Lipowicz was appointed as a member of the committee and elec-

ted chairman in the place and stead of Mr. John L. Karle.

During the month of January and February, 1927, the commission held three hearings both in New York City and in Albany and took testimony of the witnesses in behalf of the chiropractors who desire that their practice shall be regulated by the statute on the one hand and on behalf of certain medical societies, education and health officials on the other hand, who oppose any legislation on the subject.

The subject matter of investigation by this committee is an important one. For a number of years an effort has been made to enact legislation legalizing the practice of chiropractic in the State of New York. Sufficient time has not elapsed in which to give the subject matter the time and attention it requires.

In the consideration of this subject necessarily the educational qualifications of those now practicing chiropractic must be included. The committee has as yet been unable to determine just what such qualifications should be.

The committee, therefore, makes no recommendation regarding the enactment of any legislation and submits to the legislature all the facts as above stated and the question as to whether or not the committee shall be given further time to the study of this work.

**EDITOR'S NOTE** Although the Committee made no recommendation regarding chiropractic legislation, yet the chiropractors pressed the passage of a bill which progressed in the Assembly so far as to be put in the Rules Committee where it remained when the Legislature adjourned.

## JEFFERSON COUNTY MEDICAL SOCIETY

The following resolution was passed on March 10, 1927 by the Medical Society of Jefferson County —

Whereas the use of contraceptive materials in a limited way seems about to be legalized, and

Whereas, the handling of such materials by retail druggists tends to indiscriminate sale directly to the public, and consequently to illegitimate and harmful use, and

Whereas, distribution directly from manufacturers or wholesalers to physicians—and to physicians only—would tend to control the use of these materials for proper and legitimate use,

Be it resolved, that this Medical Society of

the County of Jefferson place itself on record as being strongly opposed to the distribution of contraceptive materials, especially the newer types, through local drug-stores

Be it resolved, that not only will we ourselves refrain from asking local stores to stock such supplies, but we will endeavor, by every means, to discourage and to eliminate all middlemen from handling these dangerous products

Be it further resolved, that a copy of this resolution, together with copies of the letters concerned, be sent, through the President of our District Branch, to the Council of the State Society, and another copy to the Editor of the State Journal, in the hope that this matter may be brought to the attention of every county society

---

 QUEENS COUNTY MEDICAL SOCIETY

The regular meeting of the Medical Society of the County of Queens was held at the Jamaica Lodge, I O O F No 247, 159-29 90th Avenue, on February 25th, 1927 with President Joseph S Thomas, in the chair

The minutes of the January meeting, as published in the Bulletin, were approved

The chair called the attention of the members to the Anti-vaccination Bill, introduced by Senator Kennedy of Queens and suggested that letters in opposition to the measure be sent to our representatives and assemblymen

Attention was again called to the summer camp for the Boy Scouts of the Borough of Queens and the members of the Society were urged, so far as they could conveniently do so, to volunteer to spend one or more weeks in attendance at the camp

The following applications for membership, having been approved by the Censors and recommended for election, were, on motion, duly elected by ballot cast by the Secretary

Erwin Beckhard, M D, 40-69 94th Street, Elmhurst, L I

Joseph Desane, M D, 94 Broadway, Flushing, L I

Neil Fitch Forbes, M D, 327 Jamaica Avenue, Long Island City

Hyman Fried M D, 101-01 Flynn Avenue, Howard Beach, L I

Herbert Gordon, M D, 179-B 66th Street, Arverne, L I

Victor W Higgins, M D, 115-61 Farmers Boulevard, St Albans, L I

Jacob Kroll, M D, 443 Jamaica Avenue, Long Island City

Charles Edward Nagel, M D, 3447 90th Street, Jackson Heights

David Michael Raskind, M D, 2906 21st Street, Astoria, L I

A Xernes Rossien, M D, 119-21 Metropolitan Avenue, Kew Gardens

Geysa Sarkany, M D, 22-11 29th Street, Long Island City

Jack Sarnoff, M D, 2407 38th Street, Astoria, L I

Harry King Stone, M D, 6201 39th Avenue, Woodside, L I

James R Waugh, M D, 39 163rd Street, Jamaica, L I

The following scientific program was presented

Paper "Drug Eruptions," by George McKee, M D The speaker emphasized the necessity of always being on the guard for eruptions due to drugs whether administered by mouth or injection When in doubt, the drug may be discontinued, whereupon the eruption will disappear Referring to arsenic, the appearance of an acute erythema is an important indication of danger in administration of the drug The early appearance of an eruption in a salvasan administration, if due to the drug, is a warning against possible dangerous effects Even herpes zoster may be due to arsenic The earlier symptoms may be localized erythema becoming general with a development of a dermatitis of the macula-papular type Even sodium cacodylate may produce acute skin manifestation Arsenic may produce pigmentation without antecedent eruption which will be permanent or it may produce pigmentation following eruption which will not be perma-

ment Keratoses, usually on the palm of the hand, may be produced and these may develop into epithelioma

Bromide and iodide eruptions were described as also their differential diagnosis Eruptions due to hypnotics, luminal, veronal, atophan, also pyramidon and phenacetin were described It was pointed out that at the present day the general use of phenolphthalein as a laxative was a common cause of skin eruption, the typical being macules widely spread, occasionally localized, sharply defined eruptions of reddish brown color, beginning as a redness, then changing to a reddish brown and finally to a brown which might be so dark as to appear almost black The speaker cautioned physicians in prescribing drugs especially arsenicals and even bromides and iodides, to caution patients against their continuous use excepting under competent observation Also in inquiring as to drug ingestion, it was necessary to do more than to make casual inquiry, as occasionally patients were not conscious of or did not realize they were taking a drug which was objectionable thinking of it only as a tonic The paper was illustrated by lantern slides

It was followed by a discussion by Drs J Frank Fraser, Emil J Knips, Genovese, Bender, Voltz, Sarkany and closed by Dr McKee Thanks were extended by the President to Dr McKee for his interesting and valuable presentation

Paper "Difficulties in Differential Diagnosis

of Jaundice," by Carl Boettiger, M D The speaker classified jaundice as obstructive, hepatic and hemolytic, and discussed the differentiation of these types with the aid of tests for liver functions

Four cases were cited in which jaundice was the presenting symptom, in three of them tests for liver function were done At autopsy, while the type of jaundice was confirmed the actual diagnoses were all incorrect

Two of the cases proved to be primary carcinoma, one hepatic cirrhosis with acute degeneration of liver parenchyma, and one a chronic interstitial pancreatitis with inflammatory occlusion of the common duct Gross specimens of lesions were shown

Discussion by Drs E E Keet, E J Buxbaum, W H Barber, J F Fraser and closed by Dr Boettiger

Demonstration of New Instruments in Otolaryngology by Dr A J Shekter

At the end of the scientific session Dr Buxbaum made an appeal for the widow of Dr Coster Pendola, who had been recently murdered by the father of a child whom he had treated for diphtheria and the members were invited to contribute to a fund being raised in their behalf

Collation

Attendance 55

## MONROE COUNTY

The regular meeting of the Medical Society of the County of Monroe on March 15th, was devoted to the anti-diphtheria drive The speaker of the evening was Dr W H Park, Director, Bureau of Laboratories, Department of Health, City of New York, his subject being "History and Progress of the Present Drive Against Diphtheria" Dr Park gave a very interesting resume of the progress in the control of diphtheria, showing graphically the changes in morbidity and mortality rates, with the introduction of antitoxin treatment and, more recently, of toxin-antitoxin immunization From his exceptionally wide experience, Dr Park produced statistics showing the great advance in the control of diphtheria, due to the recent methods of susceptibility tests and immunization, and expressed great optimism in the result of the present campaign

Dr C G Lenhart, Chairman of the Monroe County Anti-diphtheria Committee, reported on the progress being made in Monroe County Dr Lenhart stated that about one-third of the children in the county, exclusive of Rochester, have been tested and, when indicated, immunized since the active drive started in November, 1926, and that several town health officers had notified him of funds having been appropriated to inaugurate campaigns in their respective towns in the very near future

Dr G W Goler, Health Officer of the City of Rochester, spoke briefly on the work being done in the city and stressed the great debt owed to Dr Park by all interested in this question

Drs F. W Bush, J F Gipner, C. R Pearson and L Pulsifer were elected to membership

J P HENRY, M D, Secretary

# THE DAILY PRESS

## SMOKY NEW YORK

The air of New York City was full of smoke and soot during last year's coal strike. This year's air is clear as compared with that of last year, but it is still decidedly overcast. How smoky it is, is reported in the *New York Sun* of February 10, in an article describing a self-recording electric device that shows the intensity of the sunlight. One machine was located on a roof of lower Manhattan Island, and the other ten miles down the Bay at the Hoffman's Island quarantine station. The *Sun* says:

"Yesterday was a fairly bright day in New York but on Hoffman's Island it was a fine sunny day, with the intensity of the sunshine about twice what it was in Manhattan, according to the sunlight recorders. In the city few dense smoke clouds were visible during the middle of the day, and the sun could be seen with little trouble. But there was a haze, the result primarily of the smoke that had been poured out over the city earlier in the morning by factories, laundries, steam and electric plants, apartment and tenement houses, railroad trains and harbor vessels. Here for the first time in any newspaper a graphic sunlight report, measuring the sunlight in foot candles, is given with the previous day's weather report."

"Most New Yorkers considered yesterday a fairly clear day, especially in view of the many smoke-fog days the city has suffered from this winter, but the little machine on the roof of the Marine Hospital at 67 Hudson Street was able to record what the human eye could not."

Much was said in the newspapers about the effects of the smoke on health. The *Sun* of

January 14 said editorially that the removal of the smoke would also remove one great cause of influenza, for "the fume-filled atmosphere is highly irritating to the bronchi. It causes coughs and renders the mucous membrane unduly susceptible to infection."

The *Sun* exaggerates the virulence of the smoke when it says:

"The most important immediate contribution Health Commissioner Harris can make to public well-being is to stop the defilement of the air we breathe, and it is a task which would not require extraordinary effort on his part or on the part of his subordinates."

The same editorial balances the suggestion of smoke removal against the theory of the spread of influenza by contact, and says:

"Commissioner Harris of the Health Department makes the entirely impracticable suggestion that in the season in which influenza is most prevalent sufferers from heavy colds shall be segregated. He knows that this cannot be done, even the autocratic powers of the department he heads cannot bring it about."

The suggestion of Dr. Harris is entirely right and influenza will never be controlled until it is adopted. The prevention of dysenteries by the control of the intestinal discharges seemed impractical half a century ago, but a half century in the future the human race will learn to prevent the spread of the excretions of the nose and throat as effectively as they now do those of the intestines and kidneys. When people learn to put less emphasis on sterile smoke, and more on germ-laden drops of nasal excretions, influenza will become as rare as dysentery.

## SUICIDES AMONG COLLEGE STUDENTS

The newspapers have recently recorded an epidemic of suicides among college students—about twenty-five within two or three months.

The causes of the suicides are widely discussed in the daily press, especially by ministers of the gospel who know little of mental pathology. They usually give the cause as a lack of religion and all that goes with it, within the home and the church.

The *Sun* of March 9 quotes Bishop Anderson who spoke before the annual New Jersey conference of the Methodist Episcopal church, as follows:

"One of the contributing causes is the failure

of religious instruction in the homes. Young people who grow to manhood and womanhood without any relations to vital religion will be sure to hold life cheaply.

"No people can be strong in public life if they are weak in private life. The home is the basis of organized society. Unless the home is belted in the basic virtues the nation is doomed."

"I would name as the second contributing cause of student suicides the strenuousness and tenseness of modern life. Our young people live too fast. They demand what they call a thrill. If they range the whole gamut of life

before they are out of their teens they are likely to feel there is nothing left worth while. The demand for amusement is altogether out of proportion to the demand for the solid things which make for character and enrichment of the mind.

"The third contributing cause is the emphasis upon physical pleasures and material values. We have lost the vision of tomorrow. We must hark back to vital religion and downright godliness or we lose."

What Bishop Anderson really discussed was

the failure of the preventive measures. The cause of the suicides is an unbalanced mind, usually an inferiority complex, with a feeling of failure in life. The modern church stands for inspiration in life, for the hope and expectation of Divine recognition, and for the glorious privilege of humble service. The church is therefore an antidote to suicidal tendencies, and is a means of treating the mental disease, but the causes of the disease lie in the realms of medicine, and the treatment belongs to the scientific psychiatrist.

---

## VENTILATION IN THE HOLLAND TUNNEL

Physicians and engineers recognize the menace of the automobile exhaust in confined places and the tenfold danger from the fumes of a burning automobile. The new vehicular tunnel from lower New York City to New Jersey will surely be congested with automobiles giving off exhaust fumes of all degrees of virulence, and probably an automobile will catch fire in the tunnel. The engineers have considered this possibility and have made tests of the ventilation of the tube in the presence of a fire like that of a burning automobile. One of these tests is described in the *New York Times* of March 16 as follows:

"Mr. Singstad took his visitors into an airtight exhaust fan chamber and showed them an eight-foot fan capable of pulling out the gases and bad air as fast as they accumulated. Two of these were turned on and the visitors descended to the tunnel, where they saw vents in the roof ten feet apart through which the used air escaped into the vent chamber, thence to be conducted to the great stacks in the ventilating

building and blown into the outer air a hundred feet or more above the pavement.

Members of the party found difficulty in keeping matches burning long enough to light pipes and cigars as the air rushed in from both sides of the roadway. Flashlight powder smoke passed through the roof vent so quickly that it left no odor in the tunnel.

After the commissioners and engineers had walked through the section, and had inspected the fire and flushing hydrants placed at 240-foot intervals, as well as the niches for sand and chemical fire-fighting apparatus for fighting gasoline and oil fires, engineers set off two three-minute smoke bombs, which, Mr. Singstad said, would emit gas and smoke in a volume equal to that from hundreds of automobiles or a good-sized fire. A longitudinal current carried a little of the smoke up the tunnel and into the faces of the spectators, but most of it swirled to the roof and was drawn out. The air cleared completely within a minute after the bombs burned out."

---

## ANCIENT DISEASES

Are decayed teeth, gout, and gallstones entirely modern diseases, and the result of luxurious living? The *Brooklyn Eagle* of March 10 discusses that question editorially, and says:

"Professor Arnold Sack of Heidelberg has gone through the stupendous task of making a pathological examination of 30,000 mummies from Egyptian tombs, according to a special Berlin dispatch to the *New York Times*, and one lesson from his work is that in all ages—the mummies dated from 4000 B. C. up to the Christian era—luxury of living has brought the same diseases to the luxurious: bad teeth, gout, gallstones and all the sequelæ of these modern afflictions that we know. It was easy to make the

distinction, because the tombs of the wealthy, the noble, the powerful could not be mistaken. Mummies from the peasant class showed almost perfect teeth and few traces of uric acid ailments."

However, there is an erroneous premise in the argument. The bodies of only a small proportion of peasants who died were preserved as mummies, and only the strong and healthy achieved financial success to secure their mummification. Those who were defective died a lingering death in poverty and their bodies were soon dissolved. The mummies that remain are those of the rich, but diseases probably affected the peasant at a rate far greater than the rich.

# BOOK REVIEWS

**THE CARRIER PROBLEM** By K. C. PAUL, MBBS  
12mo of 102 pages London and New York, Oxford University Press, 1926 Cloth, \$1 75 (Oxford Medical Publications)

This little book is a contribution to a field of great interest dealing as it does with one of the most important problems in the control of communicable diseases.

Special chapters are devoted to the question of Carriers in various Infectious Diseases including

Enteric Infections, Diphtheria, Meningococcal Infections, Pneumococcal Infections, Streptococcal Infections, Acute Poliomyelitis, Bacillary Dysentery and Cholera.

The volume brings the literature of the subject up to date and is therefore a welcome addition to the study of epidemiology, a domain in which our knowledge is still meagre and in which there is great opportunity for further work.

JOS C. REGAN

**INTERNATIONAL CLINICS** Edited by HENRY W. CATTELL, A M, M D Thirty-sixth Series, Volume III Octavo of 310 pages, with illustrations Philadelphia and London, J B Lippincott Company, 1926

This volume contains many brief articles of value, by American and European observers, upon medical and surgical subjects as well as some observations upon medical conditions in Italy, by the Editor and others. It is difficult to mention special articles in a brief review, but a careful study of this issue of the Clinics will repay the reader.

H M M

**ALLERGY, ASTHMA, HAY FEVER, URTICARIA AND ALLIED MANIFESTATIONS OF REACTION** BY WILLIAM W DUKE, Ph B, M D, Kansas City, Mo. With 75 Illustrations The C V Mosby Co., St. Louis, 1925 Price \$5 50

In this book are presented the basic scientific facts in connection with this subject, along with the clinical manifestations of the condition, and a description of the method of testing and treating patients suspected of having this condition.

The subject is covered in a very clear and concise manner and presents much useful information to the practitioner wishing a further insight in matters of this nature and can be read with benefit by all of us.

CHAS EDW HAMILTON

**ULTRA-VIOLET RAYS IN THE TREATMENT AND CURE OF DISEASE.** By PERCY HALL, M R C S (Eng), L R C P (Lond) with introductions by SIR HENRY GAUVAIN, M A, M D, M C. (Camb) Medical Superintendent, Lord Mayor Treloar Cripples' Hospitals and LEONARD E HILL M B (Lond), F R S, Director, Department of Applied Physiology and Hygiene. C V Mosby Company, St. Louis, Mo, 1924 Price, \$3 75

In this little volume the author has endeavored to include the fundamental principles necessary for some comprehension of the uses of light in the treatment of disease.

In our present state of knowledge, ultra-violet rays are both interesting and most important of those existing in the solar spectrum. As the author states, the time was opportune for the publication of a short work upon this subject by someone with practical knowledge.

Case reports are added showing the various clinical applications of this therapy. The reviewer feels that although there is a great value in the volume as a whole to the practitioner of medicine, still its attention as a volume to be placed in the hands of even the most

intelligent of the laity, is not practical. Possibly the author, being English, is not very familiar with reports of cures as reported and distorted in our public lay press. We feel that the scope of this volume is sufficient enough in the enlightenment of our own colleagues in revealing the wide therapeutic application of light.

B KOVEN

**THE PRIVATE PRACTITIONER AS PIONEER IN PREVENTIVE MEDICINE.** Being the Annual Oration of the Hunterian Society, 1926 By SIR GEORGE NEWMAN, K.C.B., M.D., D.C.L. Octavo of 47 pages New York, Oxford University Press, 1926 Paper, \$ 30

Many of us do not realize that it was during the eighteenth century that the medical profession began the study of epidemiology, introduced notification and disinfection as means of controlling communicable disease, advocated improved dietaries, initiated industrial welfare, began the reformation of obstetric practice, attacked systematically the problem of infant mortality, established dispensaries, hospitals and medical schools, and laid the early foundation of immunity.

Sir George Newman traces these developments in the Annual Oration of the Hunterian Society. All physicians should read his address which is published in pamphlet form, it will be found by all to be of real interest.

E. H. M.

**MASSAGE AND THERAPEUTIC EXERCISE.** By MARY McMILLAN Second Edition. 12mo of 331 pages with 17 illustrations Philadelphia and London, W B Saunders Company, 1925 Cloth \$2 50

The author of this admirable little volume has been in close association with men high in the art of reconstruction of the deformed and maimed. There are very few better equipped to write about the above physical modalities.

This volume is highly recommended both for the physician who writes the prescription and for the reconstruction aide who is to compound it or carry it out. It is short, and its text is remarkably to the point leaving out the unnecessary.

B KOVEN

**A BIPOLAR THEORY OF LIVING PROCESSES** By GEORGE W CRILE. Edited by AMY F ROWLAND Octavo of 405 pages, with illustrations New York, The Macmillan Company, 1926 Cloth, \$5 00

In this book the brilliant and ingenious Crile has presented a biologically fundamental and far-reaching theory in explanation of the living state in general, of certain intracellular intercellular and cellulose-environmental processes in particular, of decadence, disease and death. The living and non-living are compared and contrasted and some steps in the transition from non-living to living matter are suggested. The theory is clearly conceived, explicitly set forth, openly discussed and its applications to the involved problems of physiology and pathology plainly indicated, the gross result of all of which is rather astounding and somewhat bewildering.

Although some idea of this essentially simple, yet remarkably comprehensive theory may be gained by perusal of the following digest, for its comprehension the book, itself, must be read, carefully and critically, its contained assertions and cited evidence weighed and its logic analysed. If, however, the following paragraph serves to stir the interest of those who have not read the book its inclusion in this, necessarily brief, review may be justifiable.

Every living cell is electrically bipolar, the nucleus being positive and the cytoplasm negative. This bipolarity is maintained by the relative hydrogen-ion and hydroxyl-ion concentrations (acid-base balance) in nucleoplasm and cytoplasm, respectively, the lipid film separating the two (nuclear membrane), being relatively dielectric, acts as a condenser and its two surfaces are oppositely charged by the related oxidation and reduction processes continuously in progress in the cell. When the potential difference between the nucleoplasm and cytoplasm reaches a given magnitude a current traverses the film, tending to equalize the difference. This current stimulates the cell-processes in general and, of these, oxidation in particular, one result of which is restitution of the potential difference (bipolarity) by adequate ionic re-charging of the nuclear membrane. These two processes—the electric discharging and oxidative re-charging—being thus complementary and mutually sustaining, are fundamentally responsible for the automatic maintenance of cells and tissues in the living state. Similar reciprocal relations pertain between the differentiated cytoplasmic structures on the one hand and the environmental cytoplasm on the other, as well as between the whole cell and its immediate fluid environment. The rate at which this oxidative charging and electric discharging occurs varies in different cells and tissues, there probably being, for each sort, an optimum potential difference (acid-base balance) between membrane-separated portions, approximate maintenance of which is essentially normal, deviation from this normal potential maintenance occurring in disease and annulment of it (neutrality) meaning death. What has been said of the cell and its parts applies, broadly, to the entire metazoan organism and its organs, in which case the brain is predominantly positive and the liver negative.

To one who is genuinely interested in the problem it deals with the book is fascinating and richly suggestive throughout, and is even now, being widely discussed among members of the medical profession.

J. C. C.

**HYDROGEN ION CONCENTRATION OF THE BLOOD IN HEALTH AND DISEASE.** By J. HAROLD AUSTIN and GLENN E. CULLEN. Octavo of 75 pages. Baltimore, Williams and Wilkins Company, 1926. Cloth, \$2.00 (Medicine Monographs, Vol. VIII.)

This little monograph of 62 pages is divided into four chapters, the third of which is devoted to the consideration of the changes in the blood hydrogen ion concentration in a group of unrelated diseases.

The literature has been rather fully reviewed by the authors.

The clinician and laboratory worker will find a great deal of interest in this concise little presentation.

H. M. F.

**THE TREATMENT OF FRACTURES WITH NOTES UPON A FEW COMMON DISLOCATIONS.** By CHARLES LOCKE SCUDDER, A.B., Ph.B., M.D. Tenth edition, revised. Octavo of 1240 pages, with 2027 illustrations. Philadelphia and London, W. B. Saunders Company, 1926. Cloth, \$12.00.

The tenth edition of Scudder's *Treatment of Fractures* is the largest edition so far published. The book has been thoroughly rewritten and much new material has been added. The book, as the previous edition, is profusely illustrated, adding to the clarity of the text.

The author has added to the value of his book by the contributions of Joseph C. Bloodgood on the Pathology of Fracture, Frederick W. Bancroft on the Repair of Fractures and Kurt H. Thomas on Fractures of the Mandible and Maxilla. James B. Menell is quoted extensively on massage. The reviewer was quite surprised not to find under this heading some reference to diathermia and its use in fractures and dislocations.

It was quite refreshing to see considerable space devoted to the treatment of gas gangrene. The author did not make the usual mistake to say it is a rare disease of civil life.

As Collateral Reading for the medical student it should be on the list of every medical school. It points out clearly the pitfalls that a general practitioner is likely to encounter. The Chapter XLIII "The Surgeon and the Law" is of special value in this respect.

The book should also have a place as a reference volume in the library of every surgeon. The work as a whole is a great contribution to the subject of fractures and should be read by every one who comes in contact with this branch of surgery.

J. T.

**EDGAR'S PRACTICE OF OBSTETRICS FOR STUDENTS AND PRACTITIONERS OF MEDICINE.** By J. CLIFTON EDGAR. Revised by NORRIS W. VAUX. Sixth Edition. Octavo of 779 pages with 684 illustrations. Philadelphia, P. Blakiston's Son and Company, 1926. Cloth, \$8.00.

In this revised edition, we find the old new again.

There is little to criticize as this book fulfills its object admirably, bringing to us the newest attainments in the obstetrical art.

This is conveyed not only by the written word but by the numerous new and instructive illustrations.

The division of the book has been well planned and the subtitles clear, so that as a source of reference it lends itself admirably.

There are methods and advice given that are, to say the least, controversial, but still this does not distract from its general excellency.

The reviewer is happy to recommend this book not only to students but to the obstetrician.

G. W. PHELAN

**YOUR TONSILS AND ADENOIDS. What They Are and How to Take Care of Them.** By MARTIN ROSS, M.D. 12mo of 132 pages. New York and London, D. Appleton & Company, 1926. Cloth, \$1.50.

In this work the author does much to meet the growing desire on the part of the medical profession to educate the public in medical matters, and to tell patients what is the matter with them in plain understandable English.

What the adenoids and tonsils are, where they are, their diseases and treatment, the indications for, and dangers in their removal, are all considered. The question of focal infection is fully explained.

It is a well written, conservative work that can with profit be placed in the hands of our patients or their parents when they are trying to decide which one of the many courses given them by doctors and friends they had better choose with reference to their own or their children's tonsils.

JOHN W. DURKEE.

**ORTHOPÆDIC SURGERY.** By W. A. COCHRANE, M.B., Ch.B. Octavo of 528 pages, with illustrations. New York, William Wood and Company, 1926. Cloth, \$6.50.

This is a handy size volume of 500 pages, copiously illustrated and includes comment on the entire gamut of subjects embraced in the specialty. Cochrane has devoted the first part of his book to a rather complete exposition of the teachings of J. E. Goldthwait relative to the structural and functional conception of disease.

The essential message imparted is that form and use alter the physiology of many of our organs, bad posture and poor body mechanics frequently affecting the health of a patient adversely. The author classifies all individuals into four types. In a very convincing manner he shows the proclivity of the different types to different diseases. It is not only an ingenious theory, but it has a practical application relative to the rehabilitation of chronic patients.

Part II takes up the usual orthopedic problems in a regional manner. His remarks on each condition are concise, and the treatment is clearly described or ably illustrated. On the whole, this is an important volume and one will be well repaid for reading carefully and adapting to their own demands, the advice given in the first part.

DONALD E. MCKENNA.

# OUR NEIGHBORS

## THE JOURNAL OF THE MICHIGAN STATE MEDICAL SOCIETY

The Editors of the NEW YORK STATE JOURNAL OF MEDICINE are always interested in the official Journals of the sister State Medical Societies. *The Journal of the Michigan State Medical Society* for March contains the report of the Secretary-Editor of the *State Journal* for the year. That part relating to the *Journal* is of interest to New York State physicians.

The State Society had 3,065 members on December 31, 1926. The budget of the Society assigns a charge of \$2.50 to each member for his subscription to the *State Journal*, thereby allocating \$7,500 of the State Society's funds to the *Journal*. The report says:

"The total cost for the year was \$14,128.32. Subscriptions and Advertising earnings were \$16,106.40. A profit of \$1,978.08 must therefore be credited for the *Journal*."

The report further says:

"The year 1926 witnessed the completion of the Twenty-fifth Volume of *The Journal*—a quarter of a century of publication.

"This last volume consisted of 684 pages of reading matter, approximately 408 pages of advertising and index of 8 pages or a total of 1,100 pages.

"The monthly circulation has averaged 3,250 copies. With the approval of the Executive Committee a change in style, cover, type, and arrangement was effected with the beginning of our present volume. Your Editor spent much time and experimentation in this rearrangement and feels that the present form enhances the appearance of our publication and reflects to our Society's credit.

"Your Editor is not purposing to comment upon the intrinsic merits of *The Journal*. Such comments and appraisals must be forthcoming from the Council and our individual members. Our editorial ideals and aims have been and are. To afford a medium for the publication of scientific articles and the recording of scientific progress, the imparting of public health measures and achievements, editorial discussion of

scientific advancement, organizational policies and problems, fields of Society endeavor supplemented by comments upon social, economic, and individualistic events, happenings, and achievements. The effort was always to interweave a spirit of enthusiasm and increased individual activity on the part of our members to foster fraternalism and the quest for the attainment of better, extended and greater end results that proclaim progress while at the same time commendably acquitting ourselves of the implied responsibilities that warrant our Society's existence and justify its activities, lastly, to cause *The Journal* to record county and individual effort, thereby creating a historical record.

"The degree with which these purposes have been attained is not for your Editor to appraise. The verdict must emanate from our members. It has also been our desire and purpose to awaken and maintain personal interest by providing an open forum wherein members may voice opinions and suggestions as well as requests and constructive criticisms. In brief we have sought to cause *The Journal* in full degree to be the official organ of our Society. We may justly point with pride to the sustained interest that has made possible the realization of a worth-while publication that creditably reflects our Society's progressiveness.

"The Editorial duties are not inconsiderable, on the contrary they consume an increasing amount of time. With expansion in size and form additional hours are demanded in editorial preparation of articles, copy, proof reading and contact with our advertisers. Our mailing problem is one that demands close and constant attention occasioned by a large number of change of addresses. Problems that involve policy or that effect individuals or groups are always submitted to the Publication Committee. I record my expression of appreciation for this valued assistance in the editorial direction of *The Journal*."

## CARBON MONOXIDE POISONING

The extensive use of the automobile by all classes of persons results in an increasing amount of lesser degrees of carbon monoxide poisoning. Headaches and a feeling of fatigue are common symptoms of the chronic form of the poisoning. The Connecticut Weekly Health Bulletin for

February 28, discusses this health menace as follows:

"An automobile driver reported to a member of the State Department of Health Staff that after getting a new car he began to suffer head-

## THEORIES vs. FACTS

He may have had some sad experience, or he may have been just suspicious—but he maintained that it was contrary to reason to suppose that an artificial limb could be fitted by measurements alone, without the patient being required to go to the factory of the limb maker. He had a hundred arguments and they were all perfectly sound.

### BUT

He did not count on the MARKS METHOD. We made him an artificial limb on the guaranty that if it were not entirely satisfactory he should come to the factory and a new limb if necessary, should be made. He never came. On the contrary, he wrote

I never dreamed that such a thing was possible. You have fitted me perfectly, far better than — and — who tried their limbs on me several times. You have a marvellous system, and it works

Thus he joined the great army of satisfied Marks patrons

(Continued from page 382)

aches for the first time in his life. A friend suggested that the heater might permit gas from the exhaust to enter the car. Removal of the heater stopped the headaches which had been caused by carbon monoxide poisoning.

"A Boston physician reports a similar experience by one of his patients in a recent number of the *Boston Medical and Surgical Journal*. In this case, however, the man finally sold the car before he was completely relieved from headaches due to carbon monoxide poisoning.

"These instances serve as a reminder of a constantly increasing hazard from the extended use of automobiles. Carbon monoxide gas is a product of incomplete combustion and is always present in the exhaust gases from an automobile. It may also come from an oil burner, from a coal burner, or indeed from any fire where insufficient air is supplied for complete combustion.

"Headache is a common experience in garages and automobile repair shops and the only practicable remedy so far developed is removal of the carbon monoxide gas either through a pipe connected with the exhaust of an automobile while the motor is running or by means of forced ventilation to take the gas out.

"Upon visiting an automobile service station recently in response to a complaint of carbon monoxide poisoning among the workers it was found that the management was considering the installation of an ozone machine on the theory that the ozone would convert the carbon monoxide into carbon dioxide which would be a harmless gas. The January Bulletin of the New York Bureau of Industrial Hygiene contains an article by a chemical engineer describing experiments in which ozone failed to reduce the amount of carbon monoxide in the atmosphere of a closed experimental room. From these experiments it is concluded that the expenditure of several hundred dollars for ozonators for use in a garage is not justified.

"The carbon monoxide problem must be attacked from the standpoint of ventilation. Whether ventilation takes the form of removing exhaust gases from an automobile through a pipe connected with the exhaust, or of removing contaminated air from the garage appears to be a secondary matter. The point is to remove the carbon monoxide by any means the engineers can find effective for doing so. Otherwise people will continue to suffer from chronic carbon monoxide poisoning in garages and automobile repair shops."

## A FAT DIET IN PREVENTING TUBERCULOSIS

When the London *Lancet* prints a three-page article on the prevention of tuberculosis by a fat diet, the presumption is that it has considerable basis. Such an article appears in the *Lancet* for January 8, from the pen of Dr. W. B. Vaile, Medical Officer to the Church Army Sanatorium for Boys, Heath End, Aldershot, England.

The article describes the author's observations regarding the fat-eating habits of children who have been exposed to tuberculosis, and the incidence of the disease among the fat eaters and those who are fat shy. Several typical family lists are given, of which the following is typical.

"Case 3—Infection was by the father, an old-standing positive case

### Fat-Eaters

Mother, 60, alive and well

Daughter, 33, alive and well

### Fat-Shy

Son, 25, died P. T. 1917

Daughter, 25, died P. T. 1922

Daughter, 21, died P. T. 1923

Son, 20, P. T. pos advanced

Daughter, 35, doubtful

"The daughter of 35 is married and living at a distance. She is said to be "delicate" and has been refused by an insurance company, but possibly on her family history.

The following paragraphs are taken from the author's further discussion of his theory.

"People who eat a few fats only are clearly fat-shy and must be so classed. They do not eat enough for their protection. Especially is this the case with ham and bacon, which, oddly enough, few of them object to, and which seem to have no protective effect whatever. That these fats are deficient in vitamins is suggestive.

"By inquiring among patients at dispensaries and elsewhere I found that the large majority were fat-shy, and further that the infection to which their resistance had yielded was often very slight and occasional, whereas the fat-eater seemed to require sudden exposure to many bacilli, usually continuing day after day for months.

"The fat-eater cannot suddenly share a bed with a consumptive, nor plunge into badly infected lodgings, nor stand the introduction into his small office of a clerk who coughs incessantly and proceeds to close every possible crack to avoid draughts. But the fat-shy cannot meet an infectious friend once a week at a club nor teach in a large airy school-room where an infectious child came for just three days.

"With the fat-eater liberties can be taken His higher resistance allows a bigger initial dose and much less care about the subsequent doses In the same way he can inhale with impunity a comparatively large dose of tubercle bacilli and increase the number much more carelessly Doses which would be fatal to the other are positively beneficial to him, helping him to build up an ever-increasing resistance He can stand anything in reason—anything,

that is, but a series of overwhelming doses to start with

"There is, I think, every reason to hope that a wider knowledge of these simple facts among the general public may lead to a great diminution of pulmonary tuberculosis At present we are dependent for our safety on the intelligence and the goodwill of the infectious person We exhort him to protect us Here is a simple way of protecting ourselves"

## WOMAN'S AUXILIARY TO THE MEDICAL SOCIETY OF NEW JERSEY

The Medical Society of the State of New York has not yet given serious consideration to the formation of a Woman's Auxiliary, but our sister state of New Jersey has adopted the movement and is promoting it actively as is shown by the following extracts from the *Journal of the Medical Society of New Jersey* for March —*Editor's note*

"At the last annual meeting of the State Medical Society, the House of Delegates determined upon the formation of a Woman's Auxiliary, and appointed a special committee on organization, with Mrs Samuel Barbash, of Atlantic City, as Chairman Immediately afterward, the newly elected president, Dr James S Green, issued a

letter to the presidents of all the county medical societies requesting them to cooperate in this work, and to start off by appointing a local representative—preferably the wife of the county society president—to aid in organization plans

"Two possible modes of procedure suggested themselves to form a state society auxiliary and then develop county branches, or, to organize auxiliaries to the county medical societies and then amalgamate these into a state body at the time of the next annual convention of the State Medical Society After due consideration of the amount of time and labor required to effect the ultimate purpose, the second plan was decided upon"

## LOCAL ANESTHESIA FOR TREATMENT OF FRACTURES

Three methods of anesthesia are proposed for obtaining muscular relaxation during the reduction of fractures, 1 general, 2 spinal, and 3 local. The following abstract from an article in the West Virginia Medical Journal for March gives an excellent account of the method of local anesthesia by Dr W S Magill of Morgantown—*Editorial note*

"The present trend of practice in this country is insisting more and more on the exact, complete and prompt reduction of every fracture under control of the X-ray picture, first for demonstrative diagnosis, and secondly for practical evidence of its complete reduction and maintenance during the healing process

"Such therapy is considered, by reason of its requirement of complete reduction and the time necessary for X-ray plates before and after reduction, to make necessary a complete anesthesia—more exactly analgesia—throughout the entire period of making the diagnosis, effecting complete reduction, making the requisite apparatus for immobilization, etc., as well as the exposures, before and after, for the X-ray plates

"The time of accomplishing all of these things is so great, that where a general anesthetic is used, it involves all of the undesirable symptoms, dangers and after effects of any such prolonged deep anesthesia. For reduction of fractures under general anesthesia the deep unconscious state is absolutely necessary

"All the requisites for fracture therapy under complete analgesia, without requirement of general anesthesia, and for any period of time desired are met by the use of local anesthesia

"For all non-complicated fractures this local analgesia is easily effected by use of suitable needle and syringe, pushing even into

the marrow of the bone, at the site of fracture, and in close approximation about it, a small quantity of a two per cent solution of novocaine-adrenalin in distilled water. In the vicinity, make also a few intra-muscular injections with this same solution, and in case the fracture be juxta-articular, make at least a small injection of this solution into the joint (intra-articular)

"In about fifteen minutes time there results a complete analgesia, with complete muscular relaxation and the suppression of all reflex contractions during the entire time of the requisite manipulations for the complete reduction maintenance and control of all such fractures

"Such procedure is not new. In fact, it is extensively used by a number of surgeons, but it seems this local anesthesia in fracture therapy is not sufficiently known to the general practitioner for his use to anything like the extent the method merits

"During the European war in Russia, where many of the first aid stations of the front line were insufficiently manned, this method of analgesia was very widely used, as it permitted the surgeon without other skilled assistant to accomplish rapidly, thoroughly and painlessly the reduction of all such fractures, and the long persisting analgesia was also of great value in permitting the immediate transportation of such patients, as soon as the fracture was completely immobilized, to the rear and even directly into evacuation station, as he was free from pain and completely, assured of all necessary care of his fracture for at least a week

"In all the Industrial work of our state, it would seem that the first attending surgeon would find the local anesthesia invaluable for his immediate care of fractures of this nature, and in hospital practice it should be a preferred method for the reasons stated, and even might well become the established routine of procedure"

# DR. BRUSH'S Kumyss

Reg U S Pat. Off

It Is Sometimes Asked  
What Is Dr. Brush's Kumyss?

Dr. Brush's Kumyss is made from pure cow's milk which has been caused to undergo a vinous fermentation, thereby adding three new elements, alcohol, carbonic and lactic acids. It is delightfully effervescent, with a pleasant acid flavor, thirst quenching, healthful nourishing and easily digested. Dr. Brush's Kumyss is never lumpy, all lumpy Kumyss should be avoided as unwholesome.

Introduced by E. F. Brush, M. D., in 1876, as Dr. Brush's Kumyss, it immediately won the endorsement of the medical profession. Ever since, it has been recommended by them in all forms of digestive and intestinal troubles, anemia, wasting diseases, old age and all forms of weakness.

Do not confuse Dr. Brush's Kumyss with buttermilk or any milk preparation which is thick and unpleasant to the taste.

Samples without charge on receipt of request.

## NEW ULTRA VIOLET LAMP

Every progressive physician today cannot help but be interested in Ultra Violet Light Therapy Carbon Arc Light, long recognized as the source of artificial light that closest resembles natural sunlight, is now available at comparatively low cost. The Twin Arc Tropic Sun Lamp advertised on page xiii sells for only \$200. It is handsome in appearance—sturdy in construction and the "fool proof" patented automatic lighting mechanism is the acme of simplicity and ease in operation. The employment of twin arcs gives you 75 per cent greater efficiency than was possible with the old single arc. Furthermore if you are located in Manhattan, Brooklyn or Bronx you can have this lamp demonstrated in your own office by calling Ashland 6524. No obligation on your part is incurred by a request for a demonstration. See advertisement on page xiii.—Adv

**WANTED**—Salaried appointments for Class A physicians in all branches of the medical profession. Let us put you in touch with the best man for your opening. Our nationwide connections enable us to give superior service. Aznoe's National Physicians' Exchange, 30 North Michigan Chicago. Est. 1895. Member the Chicago Association of Commerce.

West End Avenue (corner of 85th Street, New York City) Well established X Ray man would like to share his office with gastroenterologist or roentgenologist. Phone Snsquehanna 7823—between 5 and 7 P.M.

**FOR SALE**—Medical Periodicals complete files, odd volumes and back copies, also books on the History of Medicine. We purchase unbound and bound Medical and Scientific Journals. B. Login & Son 29 East 21st St., New York.

**WANTED**—Doctor, splendid location, two churches, high school, good state roads, prosperous community that needs a doctor at once. For information, write Wm. Lobeck, Supt., Borden's Condensary, North Lawrence, New York.

"A young specialist in Metabolism (Diabetes, Blood Pressure, Nephritis) of excellent training, at present a member of a large and well known N. Y. Hospital desires further affiliation with a small Grade A Hospital in N. Y. City where he may develop a metabolic clinic and do research work. Best references can be furnished and can interest one of the greatest authorities as co-worker. Address Box 79, Care New York State Journal of Medicine.

**WANTED**—Institutional position—Preferably with house supplied, no psychiatry. Gentle married 27, Grade A 2 years internship, some tuberculosis experience, 4 years general practice. New York license, asks \$3,500.00. Address Box 78, New York State Journal of Medicine.

**FOR SALE** Estate in the Mohawk Valley at Canajoharie. Commands an enviable location for a private sanitarium convenient to Albany, Utica, Sharon Springs, and Cooperstown. House is set in seven acres of land, three of which are gardens. Home has five large masters' bedrooms, six baths, showers, lavatory, sleeping porches, large living room, music room, solarium, kitchen large and airy, with all electrical attachments for refrigerator, range, washer and ironer, pantries, maid's dining room, inextinguishable water supply, hot water heating, three car garage, chauffeur's apartment, other buildings on place. Extremely low asking price. Inquire by letter to owner C. G. Lipe 124 East 55th Street, New York City.

**TWO PRIVATE HOSPITALS**  
For Sale or Lease

Located in the Borough of Manhattan, New York City. Both are licensed hospitals equipped for Surgical and Maternity work, and were established 18 years ago. They contain 14 beds and 28 beds respectively. Will sell or lease together, or separately to suit. Reason for selling, proprietor is ordered West. For particulars apply Box 79, New York State Journal of Medicine.

## THE ELECTROCARDIOGRAPH

The *Virginia Medical Monthly* for March discusses the electrocardiograph in the following editorial—EDITOR'S NOTE

"The electrocardiograph is not an instrument for detecting valvular heart lesions, as such. There is no characteristic tracing of a mitral stenosis, a mitral regurgitation, of an aortic stenosis or aortic regurgitation. It does not record in any manner auscultatory phenomena of the heart. It does not denote the presence of a murmur or a bruit. It does not indicate the quality, time relation, or absence of heart sounds or heart murmurs. These physical factors of heart operation which are so valuable in physical diagnosis remain in the domain of auscultation.

"It is only when cardiac muscular phenomena are to be investigated and recorded that one turns to electrocardiographic tracings. In the display of these important events, as disclosed in the cardiac cycle, the cardiopathic examination may be considerably added to by a proper interpretation of the tracings of the three leads of the electrocardiogram. The widespread use of the electrocardiograph is reason enough for a brief comment upon its tracings at this time. But it must not be taken to be a method that will ever supplant the ancient and honorable physical examination—by inspection, palpation, percussion and auscultation. Nor can it ever be used as a substitute for a discriminating judgment in dealing with cardiac disorders. There is reasonable basis for the position

that the expert in physical diagnosis, well seasoned in practice and grounded, by contact with a large number of heart patients, in the knowledge resulting from an imperious urge of cardiac symptoms, will always be the court of surest resort, if ever a choice between the skilled clinician or the pure electrocardiographer arises. The fact is that, in our opinion, no electrocardiographer or cardiologist, as such, is best fitted to diagnose and treat the cardiopath, unless such a specialistic limitation is founded upon a wide experience in general medicine. In fact, a heart specialist can never get away from general internal medicine if he is to be the best sort of a heart specialist.

"Sir Thomas Lewis may be taken as a foremost worker in electrocardiography. His published work upon this subject should be read carefully. His little book, published in 1913, entitled 'Clinical Electrocardiography' is a careful and succinct exposition of the subject. He wrote then that electrocardiography 'is a direct means of examining the all essential heart muscle,' and this may be considered the function of electrocardiography in heart studies. By its use, one may analyze common heart muscle disturbances and determine the mechanism of disordered heart action. The observation that an electrocardiographic study is rarely superfluous will not be questioned because every added inquiry that may enable one to more nearly understand the nature of cardiac disturbance is desirable."

## Stubborn Atrophic Rhinitis!

A characteristic of Atrophic Rhinitis is the difficulty with which it is made to yield to treatment.

It is recommended that a thorough cleansing of the nasal passages by the production of Hyperemia is a routine indication.

Wherever this method is employed, and seems indicated, the Nichols Nasal Syphon will afford thorough cleansing in a safe, sane, and really scientific manner.

*Our booklet on Nasal Therapy is sent free, if written!*

Nichols Nasal Syphon, Inc., 159 East 34th Street, New York City

## THE FISHER METHOD OF COLON IRRIGATION

Irrigation as Employed in the Treatment of Chronic Intestinal Stasis by Recently Developed Technique

"We are fond of thinking how modern science is wiping out plagues and extending the field of preventive medicine. It is then with something of a shock when one reads that too many physicians look with coldness on modern discoveries. In consequence only a limited number of people are receiving the best that science can afford." (From an editorial in THE NEW YORK STATE MEDICAL JOURNAL.)

For proper irrigation we must bear in mind the wise comment of J P Thornley, M D (in the *Medical Times*, July, 1924) "Like everything else, this simple little operation may be well done or poorly done and, except by accident, it is not one that any fool can do well. This the patient will appreciate more than the surgeon."

The Apparatus as employed in the FISHER METHOD of COLON IRRIGATION is fully described in our booklet, sent on request. See ad page xxvi.—Adv

## THE SPIRELLA FIGURE

The Spirella Figure Training and Supporting Garments embody peculiar features which belong to that particular brand exclusively.

They support the part and work in harmony with the muscles, joints and bones and permit full freedom of motion and normal pose, thereby promoting health and beauty of figure, especially in women.

While in Europe last spring Mr Grinager, International Designer of the

garments, had the privilege of demonstrating the principles of Spirella Designs before the Institute of Hygiene of London, England, meeting some of the greatest medical men of the United Kingdom. Since 1911, each successive year Spirella Garments, with their improvements, have received the Certificate of Merit of this Institute.

An illustration and description of the merits of the Spirella Maternity Corsets are found on page ix of this issue.—Adv

## DIATHERMY

A simple, complete, compact machine, with all current modalities, including electrical surgical cutting is offered you on the part-payment plan by the well known firm of Waste & Bartlett Mfg Co. See their advertisement on page xvi.—Adv

## NEW YORK MEDICAL EXCHANGE

This Exchange, located at 489 Fifth Avenue, New York City, has just been started in New York City for the benefit of physicians and other members of the medical profession.

The director is Miss M P Edgerly, a young woman well-versed in the medical field. She is young enough to be enthusiastic and experienced enough to understand the problems of the doctors, laboratory and X-ray technicians, nurses, medical secretaries, and other professional people who come to her to find congenial employment. She has been very successful in finding the right person for the the right place.

Miss Edgerly also takes complete charge of the sale of practices. Her office is conveniently located opposite the library, but while it is in and of New York, it is nation-wide in its scope. See advertisement, page xxvi.—Adv

SAVE \$30.00

THOMAS NELSON & SONS' page advertisement which appeared in the March 1, 1927, issue of this JOURNAL, offers such an opportunity. Sign their coupon herewith and mail to them for details.

## TUBERCULOSIS WORK IN CATTARAUGUS COUNTY\*

By ALLEN K KRAUSE, M D, BALTIMORE, MD

THE plan of the anti-tuberculosis work in Cattaraugus County is admirable, and as simple and perfect as can be. At this late day, there can be no quarrel as to how to prevent tuberculosis, or how best to treat it. We know, for instance, that we must find practically every significant case, just as we know that we must see to it that all cases have the proper care, and we may be perfectly certain that if all this could be done in a community for, say, a generation, tuberculosis would come near to disappearing in that community. We know also through what agencies we may best find the cases as well as treat them. The whole question is to know how to do all this work in a county such as Cattaraugus—how best to make these agencies effective. And with all this, as you know, although the Cattaraugus Board of Health is by no means the only county board of health organized on this basis nevertheless it has perhaps more opportunities than any other ever had to devise proper programs. And I approach the whole subject from this point of view.

*Terminology*—No case should be called tuberculosis unless it can be proved to be so, and, in all reports of case-finding or discussions concerning case-finding, it would probably be better to drop the term "arrested." "Arrested" is not a diagnostic term. "Arrested" is a term that was coined to designate a well-understood type of progress that occurs during treatment. It assumes always that a case has been under treatment for tuberculosis, and that the case has come to a standstill and is therefore called "arrested." But surely you cannot tell, merely by examining a case for the first time in the routine of diagnosis, that the patient may or may not have been treated for tuberculosis, or indeed that he may or may not have been ill even with tuberculosis in the past. There may be a presumption, and very frequently is a presumption, that the person has "arrested"

tuberculosis, but without a definite positive history, and often this is impossible to get, "arrested" tuberculosis must always remain a presumption. Therefore, the term should not be used in this connection. Let us call a condition "healed tuberculosis," or "latent tuberculosis," or "inactive tuberculosis," or some other diagnostic term, but do not call it "arrested tuberculosis."

*Infection, Morbidity and Mortality*—There are three phases of tuberculosis about which the Cattaraugus Health Demonstration should give us competent information. It must find out, first, what is the incidence of tuberculous infection in the community. This can be determined with only a very slight error. It is manifestly impracticable to examine every person in Cattaraugus County, but cross-sections of the population can be examined and tested. In general, we may always expect to obtain a pretty accurate idea of the incidence of infection.

Second, comes the incidence of mortality. Granted that diagnosis in practice is reasonably efficient, the data of mortality in any community may always be assumed to represent the most accurate information concerning tuberculosis that is obtainable.

But between mortality and infection lies the great shadow-land of morbidity, which is perhaps the most important phase of tuberculosis about which we like to know something. We would know how much morbidity can be expected to develop from a certain sum-total of infection, for it is infection which must originate morbidity, and, again, how much morbidity develops year after year from that amount of morbidity that remains on the ground, as it were, for it is plain that practically all infection originates out of existing morbidity. Morbidity is simply another degree of what we call tuberculous infection, originating the latter and again being originated by it. As a matter of fact, accurate knowledge of morbidity from tuberculosis remains practically non-

\*A revision of stenographic notes of an address delivered at a public meeting of the Milbank Memorial Fund Demonstrations, New York City, January 19, 1927.

existent anywhere, yet I believe that the Health Demonstration of Cattaraugus County has the opportunity to determine it for the first time.

It must be plain that in any consideration of morbidity we are interested almost wholly in the active case. Therefore, practically all statistics of morbidity should comprehend and be interested in only the active cases. The remarkable thing about the active tuberculosis in Cattaraugus County is that since the Health Demonstration has been on the ground, the number of cases of active disease has held steady, 154 in 1924, 151 in 1925, 157 in 1926. These are figures taken from the tuberculosis register at the end of each of the three years. We may therefore assume that they represent the number of cases actually in existence at any time and at all times during the three years. They may therefore be considered as denoting what we may call the "fixed morbidity" or "continuing morbidity" for the County.

How does this amount of tuberculosis compare with what was known to exist before the Demonstration? You have heard that the physicians of Cattaraugus had previously reported an average of 75 cases annually. I believe that most of these must be conceived of as having been active. Therefore, it seems to me that, with of course a balancing of all factors here, we may say that 75 cases annually is perhaps the amount of active tuberculosis that was known about, or registered, or reported before the Demonstration opened. Therefore, also, I would measure the contribution of the Demonstration to case-finding as having about doubled the number of known active cases of tuberculosis in Cattaraugus.

One of the most important features of any organized tuberculosis work must be always the search for contacts and the proper disposition of these. It is fundamental here that all contacts be examined for the possibility of tuberculosis, and the effectiveness of any tuberculosis service may be judged by its success in getting contacts to the proper agencies for diagnosis, and afterward by the completeness with which contacts follow instructions.

It was not possible at the time of my visit to estimate how effectively the Tuberculosis Service has been carried on in this respect, for at the time of my visit the figures on the clinical and nursing record sheets as to the number of contacts that had been found and advised had not been tabulated. Therefore, without this information we are unable to estimate what proportion of the total number of contacts that exist have been examined and are following instructions. However, we do know what proportion of examined contacts have been found to be tuberculous, and this has been roughly about 5 per cent of a total of about 500 contacts.

In order to judge proportionally the effi-

ciency of any service in respect to tuberculosis contacts, we must have four essential items of information. These are (1) The number of contacts that have been found and have been advised to come to the clinics. (2) The number of these who really go to the clinics. (3) How many of these have anatomical or biological (tuberculin test) evidences of tuberculosis. (4) How many have active tuberculosis, that is, tuberculosis with symptoms or disability.

Tuberculosis work among children is, of course, always relatively easy. It is the work with adults that is particularly difficult, and, as I see it, the main problem in Cattaraugus County or one for any County Board of Health, is to devise methods of approach, or practice, or control, etc., with the adult population. Remember, it is the adult, not the child, that is ordinarily the infectious case, and you will at once see the importance of getting hold of all adult cases, for these represent the main sources of infection. Experience in Cattaraugus has been no exception to the rule. Children form by far the larger part of the population that has been examined and put under control, while it has been found difficult to get a good proportion of the adults to follow instructions. However, the Tuberculosis Service is thoroughly alive to this situation, and is taking means to improve it, and there is little doubt that it is improving in its success in handling adults. One feature that cannot help impressing the observer is the great opportunity which case-finding in tuberculosis provides for the public health nurse to detect other diseases in their early stages. After all, tuberculosis in Cattaraugus County is a relatively minor disease. At present, it stands about seventh as a cause of death there. The success of the demonstration depends quite materially upon holding the good will of the physicians, and in the present stage of the development of the undertaking this means that the official examiners and the public health nurses must confine their interests and examinations between the neck and the midriff, that is, confine their attention largely to pulmonary tuberculosis.

This cannot help but result in the inability of the public health nurse in her daily rounds to detect and report in other conditions that may be significant. All of us talk of saving lives. For the medical profession and the people alike the saving of lives must, at bottom, be the main justification of the present activities in Cattaraugus County. We at once think, in this connection, of the many chances of the visiting nurse to pick up, at the first sign of trouble, numerous diseases, within the home which she may be visiting. For instance, in ordinary gossip with the housewife, she should always be expected and encouraged to talk about the

family's health, and here she would frequently, no doubt, learn about the first traces or symptoms of conditions that suggest rodent ulcer, or diabetes, or Bright's disease. And here would seem to lie her opportunity, in getting such patients to their physicians and the clinic so that a diagnosis of the disease could be made at a time when the patient would have the best chance of recovery.

All this is a great opportunity, and one that should not be missed. But what stands in the way, to a great extent, is the attitude of the physicians, who do not wish the Demonstration, that is, the Demonstration's nurses, to do any work of this kind that transgresses the limits of the chest. Why is this? Of course, I cannot go into the whole question of the general attitude of the medical profession toward any enterprise of this kind, except to say that an attitude such as I have mentioned is one that is natural and only to be expected. Why, though, do the physicians accept tuberculosis work, while they may object to any active interest on the part of the nurses that may go outside tuberculosis? Simply, I believe, because for years we have had a campaign on tuberculosis. The physicians have been taught that the diagnosis of tuberculosis requires rather special methods or technique. For a generation they have been educated up to the necessity of tuberculosis examinations by specialists, and have been educated down, as it were, to their own incompetence in the matter, —a thing that I have always deplored because of my belief that it lies entirely outside the facts of the case, but nevertheless the circumstance remains true. Accordingly, the medical profession has become perfectly willing to allow for tuberculosis outside activities which might presumably infringe upon their interests, but I cannot conceive of another disease besides tuberculosis for which they would be as tolerant, except perhaps the acute venereal diseases. One of the main encouraging and impressive features of the Demonstration is the certain evidence that the interest of the physicians in the Demonstration, and their co-operation with it in tuberculosis work, are continually increasing. The Tuberculosis Service lists four types of sources of tuberculosis cases. These are (1) The public health nurse, (2) the physicians, (3) publicity, (4) what are called "other sources." At my request, Miss King, statistician of the Bureau, has charted the tuberculosis cases as regards their source, for the several years of the Demonstration. These charts show that of all the sources the physicians form the only one which has constantly increased throughout the County, that is, every year they have been referring a larger proportion of cases to the clinics.

When we come to the matter of treatment,

we approach the most difficult phase of all this work. You have heard of the 494 cases being kept track of at the end of 1926. Of these, 235 were under home treatment, while the rest, 259, were under more or less supervision. The presumption is that they were under very little supervision. When we try to find out how many people are really being taken care of, we find that it checks about as follows. About one quarter of the 235 under home treatment, who have agreed to abide by the regulations of the Demonstration, cannot be reached for a good part of the year, because of their inaccessibility resulting from the heavy snows and the poor condition of the roads in winter and spring, and the presumption therefore is that one quarter of these patients are not under treatment at all during a good part of the year. The nurses try to keep in touch with these shut-ins by letter, but replies are few. You may ask, "Why not use the telephone?" The answer is that contact by telephone becomes impracticable for a very human reason. Party-line service prevails in Cattaraugus County, I have been told that there are as many as twenty-four parties on one line. And a rural patient will simply not discuss health matters on a party-line telephone, on which other subscribers might be "listening in." So this cuts off one way in which the patients might be reached.

One practical point of procedure which the Demonstration has thus far shown definitely is that in the rural districts the public health nurse must stand exactly in her profession as the county doctor stands in his. He must be a general practitioner of medicine, and she a general practitioner of nursing. Greater specialization simply will not work. Economically and practically it is impossible. This, it seems to me, is settled.

Again, in the distribution of those duties which, in the city, are generally referred to so called social service, it would appear that in the country the nurse must take to herself a good deal. There are only two social workers in Cattaraugus. These are attached to a voluntary agency, yet work with the utmost co-operation with the personnel of the Board of Health. In the ordinary home treatment of tuberculosis, one element that must often receive great attention, and frequently more than anything else, is the provision of relief. In the city, this falls within the province of the social worker, who can see to that rearrangement of the home which is necessary in practically every case. Now the nurse, in going into the home and preparing to treat her case of tuberculosis, can certainly not start this case on treatment and drop everything that may not, because of technique or plan, come within her province, and say that she must first get the social worker on the job. In remote districts

at certain times of the year, it may take days or weeks for one of the two social workers to get there, and it is not good for the morale of the patient, or indeed of the nurse, to have to wait quite a time before the treatment and care really get under way. It certainly must mean much for the future of any case to have treatment instituted immediately after diagnosis is made. The only solution of this situation would seem to be to arrange things so that in the rural districts, at least, the public health nurse be permitted to function along several lines which now are followed by the social worker.

It strikes me that we might divide the service in Cattaraugus County in some such fashion as this. Have every kind of work, no matter whether theoretically or professionally it is what we think of as social work, come under the nurse wherever and whenever it touches health or hygiene. Empower her to proceed at once under, of course, very definite instructions. If she cannot make a certain decision at the time—such a situation may confront her—have her get in touch with the Medical Director. Let the social workers do all that social work that pertains to the adjustment of legal matters, for instance, the working out of the legal aspects of a psychiatric case or in the disposition of orphan children. In other words, refer to her everything that does not pertain strictly to medicine. This plan in Cattaraugus would work better for both the patients and the Bureau than the present one. If we divide off too sharply the duties of the public health nurse—there are fifteen of these there—from the duties of the social worker, and say that one may not infringe upon the domain of the other, we are bound to have a good deal of friction between the two, and in any event the patient will frequently suffer. It should be said, however, that in Cattaraugus the public health nurses and the social workers are pulling together remarkably well.

Some provision other than exists at present must be made for the relief of patients under treatment. The ordinary tuberculosis patient is one for whom any prolonged limitation of earnings is bound to be a serious handicap, and it happens that tuberculosis in almost every case means prolonged limitation of earnings. Even though the bread-winner is on full earning capacity, and it is the housekeeper who is ill, this means that outside household service must be brought into the home and paid for. About the only avenue they have today for relief in Cattaraugus County is through the office of the County authorities who look after the poor. Ordinarily, you cannot get the tuberculosis patient, who possesses any self-respect, to accept relief through any agency that smacks of the poorhouse. You cannot, as a

matter of fact, get any one to do this—not even the down-and-out negro patients in our cities. Notwithstanding the fact that the Supervisor of the Poor of Cattaraugus County has said that in 1926 he spent more for relief work for the sick than had ever been spent before, it remains true that the one big obstacle to making effective the home treatment of tuberculosis lies in the circumstance that Cattaraugus has practically no voluntary philanthropic agencies, such as are numerous in the cities, and that nearly all financial relief must come from the Poormaster of the district. The nurses are frankly discouraged about the situation, and point to it as one that hampers them the most.

How can this be remedied?—There will have to be some agency which is frankly devoted to relief for public health purposes, and the funds distinctly set aside for that. If this means that permissive legislation will have to be secured, the quicker this is done the better. No doubt, the day is coming when every community sets aside funds for relief of those ill and disabled from all diseases. Cattaraugus might well make the start in this direction. The point is, don't let such relief smack of the poorhouse in the least degree. Conceivably, some agency like the local Board of Health might administer funds of this kind.

As a result of the school inspection of about 4,000 children in the grade schools of Olean 729 were found 10 per cent or more underweight. More complete examination of these underweight children disclosed 49 cases as being what was called "positively tuberculous." Of these 49, one was classified as bone and joint tuberculosis, 10 as pulmonary tuberculosis and the remaining 38 as having hilum tuberculosis. I have been wondering whether these figures represent the true incidence of tuberculosis among the school children. For one thing, I should expect more tuberculous adenitis, which, as is well known, is always the most common form of tuberculosis in children of school age, and, although I am told that tuberculous adenitis is peculiarly rare among the white children of Cattaraugus County, I can hardly understand the circumstance that not a single case was found among the grade school children.

Cattaraugus County would appear to have remarkably little tuberculosis among its children. One index of the opportunities for tuberculous infection in any community will always be the number of infantile deaths from tuberculosis. Reported deaths from tuberculous meningitis have of late years been so rare, as to lead one to believe that the disease has been practically nonexistent. When the 49 cases of tuberculosis among the grade-school children are analyzed only 8 are found

to have active tuberculosis. The proportions given you here today by other speakers have been as between these 8 and the total number of children *examined*, and this works out as about 0.9 per cent of the underweight children being found with tuberculosis. Perhaps a more exact idea of the amount of tuberculosis existing among the children might be had by taking the ratio between the 8 active cases and the whole number of children gone over at school inspection, that is, of the 4,000 grade-school children. This works out that only one-fifth of 1 per cent of all the children have active tuberculosis, and such a very low incidence will, I believe, better approximate the truth.

One weak point in the diagnosis of tuberculosis among the children has been that skin tests have not been made in every case. One might say, "What information would it give you, for practically every person reacts positively to the skin test?" Such a question is not to the point. In the first place, it is not true that practically every adult will react to the tuberculin test. It is not true even in the city, nor is it true for the population that ordinarily resorts to the hospital dispensary. It may be that 75 or 80 per cent of adults will react positively, yet it is not so uncommon in a city hospital to get a negative skin test in our patients. When we get negative tests, it helps us enormously in arriving at diagnoses. In Cattaraugus County I am certain that there will be many persons, both adults and children, who will not give a positive skin test. All such negative reactors may, with certain well-understood reservations, be dismissed at once as being without tuberculosis. I would therefore recommend that skin tests be done routinely and immediately upon every person up for diagnosis.

I believe that 150 active cases represents pretty well the active cases of the County. I do not believe that there are many more actives, and it is only with the "actives" that, personally, I consider that much worth while may be done. As I said before, I believe that these 150 active cases will be about twice the number of active cases that were understood to be present in Cattaraugus before the Demonstration. In other words, the Bureau's contribution has been to double the number of known actives, and that is a noteworthy achievement.

As regards the deaths, you will find that tuberculosis ran a peculiarly jagged curve for a generation in Cattaraugus County. Indeed, I have never seen a tuberculosis mortality curve quite like it. In 1920, for the first time, the Cattaraugus tuberculosis mortality line crossed that for New York State. In other words, the death-rate in Cattaraugus County was higher than it was in general for the State, —a phenomenon that has been recently noticed

as holding true for New York State in general, that is, in New York State the rural death-rate for tuberculosis has for the last seven years been higher than the urban death-rate. Accordingly, Cattaraugus simply reflects the general condition of a greater tuberculosis mortality in the country districts than in the cities of the State.

All signs point to the fact that throughout the nation there has been an enormous diminution of infection that is now becoming markedly appreciable. For instance, if we compare the tuberculosis mortality of 1925 with that of 1900, we find that for the United States conditions have improved two and a half times for the general population, and in New York City three times for the general population. But in New York City the improvement for the children has been four times, and for infants more than six times. While there are no doubt many factors which make for tuberculosis morbidity and death, it is indisputable that the earlier we go in age, the more certain we may be that factors of infection, such as dosage and repetition of infection, become more and more responsible for whatever tuberculous disease and death develop. This very significant decline of tuberculosis mortality, which is most marked in the earliest ages of life, surely suggests that the opportunities for infection have greatly decreased.

There is reason to think that, to keep up a given mortality rate in any community or geographical division, there must be a given, although unknown, amount or sum-total of infection present there. Such a factor has been authenticated for a disease like malaria. Perhaps the same factor is at work in tuberculosis, and one prime reason why deaths from tuberculosis have declined so much is that there is much less infection abroad and at large. Perhaps we are even approaching that point where the sum total of infection will, in time, become so slight as to make tuberculosis a sporadic rather than a widely diffused endemic disease. As we approach this point, we may be sure that the tuberculosis problem will, to a large extent, be solving itself, and, as said above, there are a good many signs that the situation as regards tuberculosis is taking some such shape.

The moral of all this is that we should not for any reason relax in our efforts to control tuberculosis by attempting to close up all sources of infection. Such efforts must, of course, comprise the most complete finding of cases and the taking of these under medical care at the earliest possible moment, and these are the basic purposes of the tuberculosis service in Cattaraugus. If there ever was a time to put all available money and forces into the combat against tuberculosis it is the present, when, it would seem certain, the disease is "on the

run" and thereby offers some chance of solution. Again, of all times not to relax, this is the time. The story of Germany during the war provides the best example of what happens once you neglect tuberculosis. The situation in Cattaraugus today, with its low incidence of tuberculosis, would surely seem to provide the opportunity to demonstrate decisively that tuberculosis may be really eradicated. I believe that the Demonstration should be bold enough

to set nothing short of this as its ideal, for I am of the opinion that the ideal is obtainable. The three years since the beginning of the Demonstration gives us too short a time to evaluate exactly what the Demonstration has done in the way of saving lives, but let the Demonstration have at least five years, and if necessary five more years after that, to find out whether tuberculosis can be eradicated. I believe it can be.

## THE HOSPITALIZATION PROGRAM FOR THE TUBERCULOUS—ITS PRESENT POSITION AND NEXT STEPS FOR THE FUTURE\*

By DAVID R. LYMAN, M.D.,

Superintendent of the Gaylord Farm Sanatorium, Wallingford, Connecticut.

I SHALL not take up your time by tracing the history of the development of our program of hospitalization for tuberculosis, but shall endeavor to cover the rather large order indicated in my title by asking myself a few leading questions as to this problem and then attempting to answer them.

The first question I would ask is "Should we, in the light of our experience, modify our ideas as to the desirability of the treatment of tuberculosis in institutions?"

My answer to that would be an emphatic "No!"

First, as to the advanced case. There can hardly be any question among us that hospitalization of these is not only indicated from a humanitarian standpoint, but that it is one of our most potent means for preventing the spread of tuberculosis.

The work of our dispensaries, the routine examination of families of "open" cases, and our studies in infection in childhood, especially the splendid work of Rathbun in Chautauqua County, where he is locating the chronic adult case by tracing back from the tuberculous child discovered in his school clinics, all emphasize the fact that the hospitalization of these cases is all important.

Second, as to the sanatorium being the ideal means of treatment for the early case.

If any of you should by chance have any doubts as to this, I would advise you to read the reports of Dr. Lissant Cox, the Tuberculosis Officer of Lancashire County, England. Dr. Cox's reports cover over ten years of work with a complete County unit, including three sanatoria and several dispensaries, with an expert medical staff and a force of nurses for supervision of home treatment and for the follow-up of all cases. His after-results, carefully tabulated, reveal that five years and over after discharge the sanatorium-treated cases of every

stage show an increase in permanent results ranging from twenty to forty per cent over similar types of cases treated at home.

There can be no question as to the desirability of institutional care for both types of cases.

My second question is "Has there been any change in our conception of the function of a tuberculosis hospital?"

There has been a very marked change in this. Our general idea of a sanatorium twenty years ago included a porch, a reclining chair, a rule book, three quarts of milk and six eggs daily and a chest examination once a month. That was considered a very good sanatorium regime. In fact, we usually did not examine the patients oftener than once in three months.

There has been a very marked change in our conception of the medical work of a sanatorium. In those days it was usually conducted by a sick doctor who had been hired principally because he was cheap. He was cheap because he had to take that job as he didn't have the health to take another. Most of his time was spent acting as general mechanic and bookkeeper, looking after the pigs, and keeping everybody happy. His medical work was done in his spare time.

We have a very different viewpoint today. We have found out that tuberculosis work, whether in the sanatorium or hospital, requires as high a grade of medical skill as that of the most modern general hospital. We know that our problem covers not only the existing tuberculosis but the whole general health of the patient. We must be prepared to study our patient thoroughly and seek for all physical defects that may be impairing his general health and thus contributing to the activity of his tuberculosis. We must look for and correct troubles of the eyes, teeth, throat, digestive tract, urinary tract and especially pelvic disorders in the women, so that our patients may return home with their general health at the highest possible level and not, as is often the

\*Given at the Conference of the State Charities Aid Association, New York City, January 19, 1927.

case, carrying physical handicaps that are constantly undermining their resistance

This means we must give thorough general medical service equal to that in any general medical hospital, and that we must have a medical staff and equipment to give it. In fact, we have got to give a little more in the line of medical service than a general hospital.

A physician in a hospital dealing with acute diseases of limited duration can do fairly good work, (I only say "fairly good") if his primary interest is in disease and diagnosis and he is only secondarily interested in "folks." The man in tuberculosis work can never do decent work unless interested in the patient, as an individual, just as much as in what is wrong with him, because the future health of his patient is closely affected by all that goes to make up his social and economic life. The sanatorium doctor has not only to understand tuberculosis but he has got to study and understand men and women and their problems if he is going to be of real assistance to them, and the patient in the sanatorium who hasn't a personal friend somewhere in the medical staff isn't getting the best that sanatorium can give him.

It is for these reasons that I don't think that any tuberculosis hospital can be best managed on a part-time basis, no matter what its size. That question frequently comes up—does it pay to have a full-time man for the little hospital?

I notice in New York State you have thirty-five county and municipal hospitals. Twelve of them are still under part-time management. Their beds run from twenty to fifty. Question. Does it pay to have a full-time man for that size of an institution? Well, if you get a full-time man for an institution of forty to fifty beds and you find he has any leisure time, you had better fire him. If he is doing the real work to be done and all alone, you have got somebody worth keeping and you had better raise his salary!

What about the little place of twenty or twenty-five beds? Can you use a full-time man there? You can not only use him, but you can do the best kind of work any institution can do, because in addition to taking care of his patients, he has time to go out into that community. He will be able to get in touch with your local medical profession and give consultation service to them. He will be able to act as consultant on the local hospital staff, if there be one, and improve his own medical work as well as helping the hospital. He will be able to go out into the homes of the people and examine the contacts of his own patients, and be the personal friend and advisor of the whole community and the biggest influence for public health work that community could possibly

have, and will repay his full-time salary to the community many times over.

What about advanced hospitals? There has been another great change in our ideas as to those. We used to look upon them as having only two functions, removing dangerous cases as foci of infection, and giving people a comfortable place in which to die.

Modern medicine, with the development of pneumothorax and of lung surgery has shown us that many of these cases we formerly felt were hopeless have a real chance of getting well, and if we are going to run hospitals, let's give everybody the best chance we can to get well or stop running them. There is no excuse for running them unless you do. If you provide an advanced hospital with facilities for proper care and modern treatment, you won't have just a home for the dying by any means, you will have a hospital in which many people will recover that under our old methods never had any chance at all.

My third question was, "Has there been any change in our opinion as to the type of hospital buildings best suited to the work?"

Thank Heaven, there has. One only has to think back a few years to realize that we used to get up and brag that we had accommodations at our sanatoria where we were treating human beings, and sick ones, at a cost of somewhere about one or two hundred dollars a bed! We built a shed and put a stove in it, we tried to take care of patients in abandoned street cars, anything was good enough for the patient with tuberculosis. Our main idea was not to spend any money because we expected to wipe out tuberculosis in fifteen or twenty years.

Then we made another big mistake, the biggest of all. We figured in building our early institutions that the incipient cases were all going to flock to us and that we needed only twenty-five per cent infirmary beds. There are few of us running those institutions that have not often longed to have every bed in the place where we could give infirmary care if we wanted to. There isn't a single man of us that hasn't had the painful experience of having to move patients to the cottages or shacks, because their places in the infirmary were needed for more urgent cases and then seen them relapse because of the lack of that close supervision which they should have had. Our modern sanatoria provide infirmary and semi-infirmary accommodations for from 50 per cent to 75 per cent of their population.

The type of the advanced hospital has changed in similar degree. Instead of a ward with a death room at one end and maybe one little room where some few charts or records might be kept, we expect real medical work in the hospital for advanced cases of today, and

we expect the sanatorium and the hospital alike to be equipped with X-ray and laboratory facilities to enable their medical staff to give whatever service to the patient that they think that patient may need

The era of cheap frame construction has gone and we build fireproof or semi-fireproof buildings. We no longer locate them in inaccessible spots for the sake of a few hundred feet of extra elevation, but put them near our centers of population where lessened cost of construction and of maintenance, availability of skilled medical consulting service, accessibility to families and friends and many other factors combine to insure a type of service superior to that which we can give in the more isolated places

We are getting away from two of the greatest curses of tuberculosis work,—initial cost and per capita cost. We are commencing, like any other business, to consider the returns on our investment and not exclusively the preliminary investment. The first question asked by your board of directors used to be "what is your per capita cost?" they didn't seem to care how many patients were getting well, but to think that if your per capita cost was 172, and the fellow in the other county was running for 168, that you must be wrong. Usually the fellow with the cheapest per capita work was doing the poorest work

My next question was "Are our institutions accomplishing all that we expected of them? If not, why not, and what is the remedy?"

My answer to that is an emphatic "no." We are not accomplishing anywhere near what we expected to do, because we don't get early cases, and because we don't keep them after we do get them. We expected to get them all and cure them all. We are doing neither. Now whose fault is it? First, I should say the fault is our own. My experience has been that the average institution that is doing real work always has a waiting list. I think when we have vacant beds we have got to look for the beam in our own eye before we hunt around the rest of the community. Patients are very sensitive, quick to sense whether they are the primary or secondary interest in the institution. They are not going to stay where they know they are being exploited. They are not going to stay where they know the work of the institution is being done often at the risk of the health of the patient. They are not going to stay in the institution where they do not get the nursing and care that they could get at home. In other words, when they have been at home, kept in bed by their family physician, because they had a fever and not allowed to go about at all, and then are sent to an institution where, when their temperatures are below

one hundred and one they get up and go to the bath room because there are not enough nurses, then those patients are not going to stay. That is not an unusual situation in many of the institutions of our country.

So the first fault is our own. If we bring up our standards and give our patients what they need and what they have a right to expect I think they will stay longer.

The second fault lies with the public. The public has not yet fully understood that the patient has a much better chance to get well under the regime and training of the institution than at home. We have to continue our campaign of education to teach them that.

The third fault lies with the physicians, who still to some extent advise on the basis of the few cases that have done well under home treatment, forgetting the ones who have not, or else who pattern after the old dorky who said the best way to give a woman good advice was "first to find out what she wanted to do and then tell her to do it." And knowing all patients want to stay home and that it is very popular advice to advise them to do it, I regret that medical advice is sometimes given on that basis.

The other trouble is the question of early diagnosis. How are you going to get the average man in medicine to use the means of early diagnosis we now have at hand? Why do they continue not to examine sputum? Why send a patient to pay twenty dollars for an X-ray when his sputum has never been examined? The fault does not all lie with the quacks in the medical profession. We have the beam in our own eye too. I had two patients referred to me last week, one, an advanced case, sent by one of the best men in the State who had watched him two years and had only just thought to examine his sputum, the other one an ideal early case, coming from one of the various "quacks" in our State. The latter was a little suspicious the man had tuberculosis and sent him for an X-ray and frankly wrote me he didn't know anything about tuberculosis, but the symptoms had suggested it so he had asked for an X-ray.

Our remedies for these shortcomings lie in raising the standard of our own work, in continuing the education of the public and in continuing the consultation services of all our clinics and hospitals, putting them as freely as possible at the disposal of the physicians.

One thing further that helps a great deal in this regard is to have your medical staffs of your institutions join the local medical societies, attend their meetings, and make personal contact with the physicians. Some Boards seem to think it is a waste of money for their medical superintendent to attend a

meeting in an adjoining county. They cannot spend money better.

My next question (and a most important one) is

"Can we fix a definite ratio of beds needed for any given State or locality based upon the total yearly deaths or number of cases reported?"

That is hard to do. Mr. Drolet shows that only eleven States in our Union have beds available equal to the total annual deaths. Connecticut is one of them. We have available a little over thirteen hundred beds. Our deaths for 1926 from all forms of tuberculosis were eleven hundred and eighty-six. We have therefore a few more beds than deaths.

Now, what is our situation as regards our waiting list? An active case needing bed care, if he will go to any institution where there is a vacancy, can get care in two or three weeks. The early case can be taken care of with but a short wait. It would seem, superficially, as though we were pretty well hospitalized and might have some vacant beds. I don't think so and for three reasons.

The first is that the sanatoria are becoming more popular as their service improves and people can be persuaded to go there easier. Our reported cases are fifty per cent higher than our deaths, and in Connecticut no case is reported unless the Doctor thinks he will have to sign the death certificate inside of a year and wants to be safe. So the number of active cases that need treatment is quite a good deal higher than the number of deaths.

The second cause is that the physicians are more and more using our sanatoria for purposes of diagnosis—sending us cases in which they suspect tuberculosis but where they have not the facilities for close clinical study at home. This is a service which the sanatorium can give better than the general hospital and which is certain to meet an increasing demand as the profession and the public realize its value.

In the third place, we have got to prolong our term of treatment in our sanatoria. You cannot cure tuberculosis in two or three months. You cannot train even a most intelligent patient to grasp the new conception of the values of his daily life in which he considers his health in the same routine manner as his meals, his sleep and his job in a period of a few weeks. It takes from three to four months minimum to teach a patient this and we all know it takes longer than that to get any real healing in the lung. We are now inclined to put six months as the minimum which a good early case ought to stay under treatment.

What do our statistics say? Mr. Drolet's study shows of ninety-six thousand cases in

the hospitals in this country, sixteen thousand of them left in less than one month's time, which was time and labor thrown completely away. Twenty-three thousand more left in three months, thirty-nine thousand of the ninety-six thousand were treated for a length of time, which to my mind, is utterly inadequate even to train a patient. And out of the whole number of patients, only thirty-five thousand stayed six months under treatment, and that includes the advanced and far advanced cases, as well as the early ones.

We have got to increase our length of stay in the sanatoria to get results at all. And with the need to increase the length of stay, with the increasing application of patients for sanatoria treatment, and with the doctors commencing to send in borderline cases for diagnosis, I can see no reason to fear we shall be over-hospitalized in the coming years even with a good many more beds than we have.

Now if we do insist upon it, what are we going to answer to the people who are saying now as they said twenty years ago, "If you go on with your hospitals, you are going to have a lot of vacant beds that the taxpayers are not getting any returns on." Mount McGregor has shown us definitely what use we could make of beds which are vacant, granting that we should have any. Tuberculosis is fifth in the causes of death. Heart disease and diseased arteries last year caused three times as many deaths as tuberculosis. The Metropolitan Life Insurance Company have shown how to handle cardiac cases perfectly well in the accommodations of the tuberculosis sanatorium. The routine, the buildings, the general regime, are all easily altered to take care of cardiacs. If ever we get where we have vacant beds in our tuberculosis sanatoria, there is the work lying ready at our hands.

In the case of the advanced hospitals we have always more or less used wards of chronic disease hospitals to care for advanced cases of tuberculosis. The reverse is perfectly simple. When we don't need them, we can use the separate wards to care for chronic diseases and the care of chronic disease is today the most pressing problem of the physician and social workers, who puzzle in vain over what to do with the cases nobody wants and where there is no place to send them?

The last question I asked was, "Has our labor and expenditure to date been justified fully?"

I will let you write your own answer to that. I won't take up time with it. Any way that you choose to figure it, on the value of the human life, on the value of the earnings of the patients who have gone back, on the value of the public health work done, on any basis one chooses to figure it, I think the public has

and an ample return from its money for tuberculosis

So far as I can sum up, I should say our method has been in the right direction, our work has been like all human work, imperfect. We have many faults that we have to correct

in the work we have done to date, but I can see no reason to fear that we are going to be over-hospitalized for tuberculosis for many years to come, and that certainly the ratio of a bed to a death is the minimum to which any State ought to work

## THE SIGNIFICANCE OF THE TUBERCULOSIS WORK IN CATTARAUGUS COUNTY\*

By LAWRASON BROWN, M D,

Medical Director Trudeau Sanatorium, Saranac Lake, N Y

I HAVE really come here today to learn. It is true I am of the army occupation but on a different part of the firing line. This is both an advantage and a disadvantage. I come in contact with what might be called the failures of the preventive campaign. They have developed tuberculosis in spite of all the measures instituted to prevent it. We have from time to time attempted to determine how and where they contracted their disease. At the Trudeau Sanatorium fully one-half can give no information whatever about the source of their infection and the remainder are for the most part more or less hazy about, or in complete ignorance of, its source. We know a great deal and at the same time very little about the etiology of tuberculosis.

Some years ago a very noted German would have had us believe that all pulmonary tuberculosis came from infection in childhood and indeed from milk infected with the bovine tubercle bacillus. We know now that von Behring felt strongly in regard to the type of tubercle bacillus that caused pulmonary tuberculosis, but the conception that pulmonary tuberculosis arises in an infection at a very early age, often before the fourth year, still lingers in the minds of many workers. I have always opposed such a conception, but why, I do not know. Possibly it is due to the strain of Irish blood that runs in my veins. For years I have felt that we were attacking the problem both too early and too late. By this I mean that the infections of infancy, while they play an important part in pulmonary tuberculosis, are not the infections that directly cause it. Furthermore, I would suggest that the studies we have made of well-developed pulmonary tuberculosis do not concern the most critical time of the life of the individual who is later to be found with manifest pulmonary tuberculosis.

Some years ago I suggested to Dr Lyman, at that time president of the National Tuberculosis Association, that he should stress tuberculosis work during what might be called the high-school age. Since then many interesting facts have accumulated to emphasize

the importance of this period of life. Until recently we have been strangely ignorant how tuberculosis acts in the body at this time of great strain. We have long realized that pulmonary tuberculosis and indeed other forms might remain latent for years, but when this latent infection became first discoverable by any methods at our disposal we have until recently been unable to say I mean by this that we have been unable to say when latent became manifest tuberculosis. The study of this high school age-period has been undertaken during the last few years by Rathbun in Chautauqua County, New York, and most interesting data has been collected. Chadwick in Massachusetts, and Opie and McPhedran in Philadelphia have also contributed to the data. This work has great significance for the work in Cattaraugus County and indeed for all prophylactic work. Several very interesting points have been brought out. The first concerns the selection of children for further study in regard to tuberculosis infection. The work in Cattaraugus County under Dr Douglas and Dr Jensen has clearly shown that children with loss of weight amounting to only 10 per cent show little if any more tuberculosis than the average school population. But if the loss amounts to 25 per cent, then a very large proportion are tuberculous. Hitherto the rule has been to select all children 10 per cent or more under weight. In some instances these are then given the tuberculin skin test, most often the cutaneous, less frequently the more accurate intracutaneous test. Those who react are then in some cases subjected to roentgenological examination. This method of selection, I believe is faulty, for the following reasons.

Rathbun has found that many of the children with definite X-ray lesions of pulmonary tuberculosis show no loss of weight and would be overlooked completely by a selection such as I have described. We have taken X-ray films of the entire school population of Saranac Lake and our results coincide with those of Rathbun. Furthermore, he has found several well-marked cases among the athletes, among members of the football and basketball teams. Such figures, such observations would seem to force upon us the necessity of studying

\* Given at the Conference of the State Charities Aid Association, New York City, January 19, 1927

every high-school student. They stand at the threshold of the real activities of life. But recently they have passed through puberty. Strenuous athletic games call for a vast expenditure of muscular energy. School work begins to grow more severe. I have had a growing feeling that in the next few years we shall have many observations that will force us to conclude that the time to attack adult pulmonary tuberculosis is from puberty to the 20th year. I am slowly coming to the conclusion that the great majority, I had almost said over 90 per cent, of those who are found to have pulmonary tuberculosis after the 20th year have definite discoverable signs of it in the second decade. To discover the vast majority of these cases a roentgenological examination is necessary. These cases must be discovered for they are the future parents, they are to become in some instances the silent carriers of the tubercle bacillus. I mean by this that some of them will show tubercle bacilli in their sputum only when they have at-

tacks of what we call grip. Healthy individuals still maintain their right to cough at will without covering the mouth, and physicians are often glaring examples of it, and under such conditions it requires no great imagination to picture how the tubercle bacilli may be innocently sprayed and spread. The significance of the Cattaraugus County Demonstration is that every means to prevent the spread of tuberculosis can be applied, and furthermore, that studies over a number of years will furnish us with data that can be duplicated in few other places. The population is not overwhelming, the cities are relatively small, when compared with Syracuse and a large proportion of the inhabitants rarely change their place of residence. I am, of course, only re-stating well known facts but their significance in the etiological and prophylactic studies conducted in the county cannot be over emphasized. The work already accomplished has been splendid and the work in the future holds wonderful promise.

## TUBERCULOSIS AND THE GENERAL PRACTITIONER\*

By EDWARD R. BALDWIN, M.D.,

Director Trudeau Foundation, Saranac Lake, N. Y.

ONE of the best measures for finding tuberculosis and impressing the doctor and the family with its importance is through the medium of the X-ray picture. Dr. Jensen confirmed that opinion when I visited Olean and said that many times when a family doctor was hostile to his program of doing something, he was able to show him a picture and the doctor began to take notice, then he wanted a consultation and to know more about other cases he had. This is an avenue of approach which perhaps has not been fully worked and, I hope it is being increased. I believe it is worth a good deal of money invested in that particular field.

We have several kinds of doctors. We have the doctor who belongs to the modernists or the progressives, if you like. We have the ir-reconcilable doctor, that is, the die-hard doctor, and we have the doctor who has to slave in order to keep his body and soul together and who thinks his patients belong to him and should not be disturbed.

In undertaking any sort of demonstration of a public health character, there are certain diseases that the doctor is very jealous of, but he often seems willing to have tuberculosis taken out of his hands. I think the education of the public more than the education of the doctor has had a good deal to do with the doctor's acquiescence in having clinics and examinations and so forth done in the schools

and elsewhere. When the public demands something, the doctor has to fall in line sooner or later. Under such circumstances the public health nurse must be a paragon of tact, and the consulting doctor an angel of diplomacy. We are uprooting certain settled customs of medical practice in demonstrations such as those of Cattaraugus County. I have been a country practitioner myself and know the attitude of the country doctor; I have heard him talk, and I know it is a difficult problem, and the greatest sympathy should be shown for the feelings of men who are entirely honest and have been honest in their practice and faithful to their work in midnight calls and all others, paid or unpaid. They present a problem that is worth considering and being solved sympathetically. I have a feeling that one of the helpful things that these demonstrations can do is to give such men vacations or visits to clinics and post-graduate courses. It may in many instances be a difficult thing to select the proper ones, but it is a plan which can be worked out.

I would also like to emphasize the danger of making a diagnosis of tuberculosis too soon. It is a very serious matter to make it in an adult. It is even more serious to try to make a diagnosis in a child, particularly of school age. The high school age is a most difficult one. Students dislike being examined. I heard of one place where the only way they got high school boys and girls to come to the examination was to say to them, "They want to ex-

\*Given at the Conference of the State Charities Aid Association, New York City, January 19, 1927.

amine your heart so as to see if you can go into athletic work," and they examined the lungs at the same time. Strategy has to be used, but education is the secret of success. A serial X-ray record of the school child should be made. We should know enough today about tuberculosis to be able to follow it from the time of its seeding to the time when it is beginning to blossom. I don't think we know all about the disease that we should during the adolescent age.

The X-ray film and the skin test should go hand in hand. They are both indispensable. These are things that can be done in the promotion of this investigation. Time, too, is a

very important element. It takes a year to develop tuberculosis from an infection in many instances. The amount of dosage of infection also has a good deal to do with it. But we must also remember that small dosage, plus poor environment, may develop an acute tuberculosis from a very small amount of seed.

We also wish to know whether tuberculosis revealed by an X-ray film in a child,—a small calcified focus in the lungs or rest,—for example—really develops into the adult type. We have no evidence that it does from the studies that Dr. Opie has made, but we ought to have more figures and be able to say whether or not this is going to happen.

## SIX CASES OF TRICHINOSIS IN ONE FAMILY

By MARTIN WEISS, BINGHAMTON, N. Y.

**B**EFORE entering into discussion of the six cases of Trichinosis, that I have found and treated in one family, allow me to say a few words concerning the definition, etiology and evolution of this disease.

*Definition.* An acute condition caused by the *Trichinella spiralis* and characterized by remittent fever, oedema of the face, pain and soreness in the muscles, and gastro-intestinal manifestations.

*Etiology.* *Trichinella spiralis* is the cause of the disease. The adults live in the upper part of the small intestines, the embryos pass by the lymph and blood stream to the striated muscles, and there the encysted larvae live. The male is about 1-16 in long, and the female about 1-10 in long. Trichinosis in man results from eating imperfectly cooked or raw pork containing the living *Trichinella spiralis*. Raw sausages, ham and even beef may contain living larvae.

*Evolution.* When Trichinosis meat is eaten, the cyst wall is digested in the stomach, and the worms are liberated and pass actively into the small intestines where they reach their maturity in 2 to 3 days. On about the 6th day the fertilized female burrows into the mucosa of the small intestines about 1-5 of its length and the embryos escape from the vulva which is located in the anterior portion of the worm into the tissues, and are then taken up by the lymph or blood stream and carried to the striated muscles. One female may give birth to as many as 1500 embryos in a period of six weeks, which is usually the sexual life history of a female *Trichinella spiralis*. At about the 10th day the embryos are found in the striated muscles. The embryos being smaller than a red blood corpuscle are, therefore, easily carried by the blood stream. The embryos grow very rapidly in the striated muscles, completing

their development in about 15 days. They then begin to coil up and to encyst themselves. Encystment begins about one month after infection and completes itself in about 12 weeks. These embryos may live 20 or 30 years after encystment. When meat containing cysts is eaten the cyst wall is digested, the embryo escapes, develops in the small intestines, and the cycle is again repeated.

*Resistance.* Ransom has shown that a large proportion of encysted trichinae are quickly killed at 53 degrees to 55 degrees C (130 degrees F). Salt and antiseptics penetrate the capsule slowly, especially after it is calcified.

*Occurrence.* About 2½ per cent of all hogs contain living or dead trichinae. Rats are easily infected and in slaughter houses, as high as 50 per cent are trichinosis. Billings found all rats in a slaughter house in Boston trichinosis. Experimentally guinea pigs and rabbits are easily infected.

*Case 1.* On Jan 8th, I was asked to see two members of a family of six, a mother and one boy about 12 years of age, who were confined in bed complaining of being quite sick. The mother had not been feeling well for about one week or so, on account of severe rather excruciating pains across her forehead, a fever, general bodily (grippe) pains, a diarrhea of three days duration, and most important of all oedema of both eyes. On examination, I found her heart and lungs negative, spleen was not palpable, nor was there any tenderness or rigidity in any part of her abdomen. Extremities were negative. Her gastro-intestinal symptoms were, a coated tongue and a diarrhea of 6-8 movements a day for the three days previous, and no vomiting, temperature 102 degrees, pulse 110. On the following day there was a rise in temperature and pulse, and the oedema of her eyelids were so marked, that her

eyes were completely closed. Examination of her sinuses and eyes were negative, except for a slight conjunctivitis. Late that afternoon she began to show signs of a gastric-intestinal upset, complaining of feeling nauseated, having pains over epigastrium, and finally began to vomit. She vomited several times that night, and during the next morning. The oedema of her eyelids began to improve with the application of cold compresses to her eyes, the temperature and pulse began to decline, and on the 4th day she was feeling fairly well, when her temperature and pulse took another sudden rise and the patient began to complain of pains and coldness in her calf muscles and thighs, and had chills. She was unable to stand on either her toes or heels. A blood count at that time revealed a 14,200 leucocyte count and an eosinophile count of 40 per cent the polys being decreased and the lymphocytes increased. Urinalysis was that of any acute febrile condition, showing a slight trace of albumin and a few pus cells. Examination of several specimens of stool did not show any parasites or ova. During the next

two weeks, a blood count was taken every other day, and on all examinations there was a leucocytosis an eosinophilia, a lowered poly count and an increase in large lymphocytes. Daily examinations of stools were negative. A spinal puncture was done on about the 2nd week of her illness, and the fluid examined, but was found to be free of *Trichinosis spirilli*, spinal Wassermann was negative, and the cell count normal. A resection of a piece of muscle was not done. On Jan 28th, 1926 about twenty days after the onset of her symptoms, a report was submitted that parasites resembling *Trichinella spirilli* were found in the stools. On Jan 30th I received a similar report, and on Feb 2nd ova were found. I am very sorry that a picture could not be taken of some of these, as the slides dried too quickly due to improper fixing. The complete blood picture and other clinical findings from the entire family will be given later.

*Case 2* On the same day that I was asked to see Case 1, I was also asked to see another member of the family, a boy 12 years, who was

## CLINICAL FINDINGS

*Blood Examination*

Name	Leucocytes	Polys	Lymph	Large Mononucleus	Eosin	Trans	Red Blood Count	Hemoglobin
<b>Mr John</b>								
1/26/26	10,200	45	24	6	22	3		
2/ 1/26	9,660	37	22	3	33	3		
2/ 8/26	7,800	41	29	5	24	1	4,320,000	73
<b>Elizabeth</b>								
1/25/26	17,200	40	29	3	27	1		
1/30/26	15,200	44	17	2	35	1		
2/ 6/26	13,200	38½	39	2½	20			
<b>Anna</b>

2/ 6/26	9,000	51	37	½	11½			75
2/27/26	10,100	57	24	7	6	5	4,608,000	80

Spinal fluid examination—Neg

Urine analysis—Neg

Diazo reaction negative on all urines

Feces—positive for Ova Jan. 28th, 30th and Feb 2, 1926

complaining of very severe gastro-intestinal disorders, he had been in bed for 2 days previous, with vomiting spells, excruciating abdominal pains, diarrhea, severe headaches. Oedema of the eyelids were absent and there was no soreness or tenderness in his muscles. Temperature was high and pulse rapid. On the following day he showed signs of improvement, but still vomited and had the diarrhea. After being in bed for five days he was free of all signs of symptoms of a gastro-intestinal disorder. A blood count was done on Jan 25th about 2 weeks after onset of his disease, which showed the following findings: Leucocyte count, 19,220, polymorphonuclea leucocytes, 42 per cent. Lymphocytes, 36 per cent, large mononuclears, 2 per cent, Eosinophiles, 17 per cent, Transitionals, 3 per cent. Several blood counts were done after that at intervals of one week, and the boy was watched closely for signs or symptoms but failed to reveal any.

*Case 3 to 6* Four other members of the family, father and three young girls, who complete the family, denied showing any manifestations of Trichinosis, but on having their blood examined, all showed a high leucocyte and eosinophile count. They all went on doing their daily routine work, without any discomforts. In conclusion I might say, that, this family eat but very little pork or sausages, but they do eat beef and frankfurters. They were unable to state whether this disease manifested itself after eating meat of any kind.

#### TREATMENT

- No 1—Daily high saline colonic irrigations
- No 2—Course of calomel and castor oil
- No 3—Daily injections of 1 gr thymol in 1 c.c. of sterile olive oil injected intramuscularly for seven days.
- No 4—Symptomatic
- No 5—Examining of blood, urine, spinal fluid and feces

#### POINTS OF INTEREST

No 1 There is no definite ratio between the leucocyte count and the eosinophile count.

No 2 The eosinophilia is no index to the severity of the disease.

No 3 The spirellum may be found in the stools several weeks after the onset of the disease.

No 4 The disease may begin differently in different members of the family, and some may never possess any of the pathognomonic signs of the disease, as oedema of the eye-lids, muscular pains, remittent fever, and gastro-intestinal manifestations, and so go being unrecognized.

In regard to the progress of the cases, I am pleased to write that they have all recovered. The mother having been operated upon in October, 1926, for abdominal adhesions and the children haven't had a sick day since. It might be well to include the two following blood counts on Mrs Micha

March 31, 1926 W B C, 8,000, R B C, 4,320,000, hemogl, 79%, color index, 91, polys, 59%, s lymph, 28%, l lymph, 4%, eosin, 5%, basophiles, 2%, transitionals, 2%

Sept 15, 1926 W B C, 7,400, R B C, 5,930,000, hemogl, 80%, color index, 79, polys, 71%, small lymph, 19%, large lymph, 7%, eosin, 2%, transitionals, 1%

The above blood count proves that Mrs M has clinically recovered

### SCHEME FOR NURSE EDUCATION

By ALBERT T LYTLE, MD, BUFFALO, N Y

**A** PROMINENT hospital manager is reported as publicly saying among other things—"So, while we believe in nursing education, we do not believe that the hospital should be made an appendage to a nursing school or any other kind of school." Yet he leaves the impression that he is ready and anxious to maintain a nurse training school.

Very recently the legislative body of the second largest organization of doctors of medicine in the world, among other things, resolved—"That there shall be a basically trained nurse, specifically trained for bedside work and that this training does not necessarily qualify such a nurse for executive positions of public health work without subsequent further study on her part."

It, therefore, must be conceded, viewed from the standpoints of the hospital and the physician, that the nurse must have some specific training or education.

This proposition being granted three ques-

tions arise, the answers to which materially would aid in solving the problem of the education of the nurse. They are (a) What degree of intelligence and skill, measured in terms of education, does the patient require of the nurse? (b) What degree of intelligence and skill measured in terms of education does the doctor of medicine require of the nurse as his assistant in the care of the patient? And, (c) How and to what degree should the hospital be responsible for the education of the nurse to meet such requirements?

When in 1903 the people of the State of New York through their Legislature established a legal status for trained nurses and directed the University of the State of New York to standardize nursing education, and to grant certificates to registered graduate nurses, trained nursing passed forever from classification as a trade or handicraft to that of a vocation or profession.

Conceding then that the professional practice

of nursing is no longer an industrial activity, it follows that the preparation for its practice requires educational qualifications comparable to that of any other profession and that the law only should recognize one basic type of professional nurse as it does in other professions. Fundamentally nursing is caring for the sick. Caring for the sick at the bedside carries with it transcendent individual responsibility. Therefore, the basic education for bedside nursing should be as advanced and as thorough as for any other type of nursing activity.

Conceding that the basic function of the hospital also is to care for the sick as well as to promote public health, it follows that the hospital is not instituted nor financed to function as an educational institution although so used by medical and by nursing schools.

In discussing the cost to the hospital of nurse education an astute physician and hospital manager says "The expense goes to the hospital, which, of course, eventually goes to the patients occupying the hospital or to those who support the hospital." The dean of a university nurse training school, a trained nurse of keen vision and wide experience, considers the costs of the present system of nurse education as "too costly a program for the hospitals." While, a wide-awake State official, on the other hand, states that the cost of maintenance of hospital "nurse training schools in New York State has not as yet become as burdensome as the hospital administrators would have the public think" and that the administrators "still find they can run their hospitals cheaper by using student nurses to do the work of the hospital rather than in any other way."

Nevertheless, the attitude of the managers of hospitals seems to be that the present system of nurse education is placing an unjustifiable financial burden on the hospital. To the student of medical economics their contention is warranted as the widening field of nurse activity not only requires much greater educational preparation than formerly but probably the end is yet nowhere near attained.

The most ardent opponent of more advanced nurse education without a scintilla of doubt would consider the nursing needs of the patient to be the paramount issue in the education of the nurse. Leaving out any consideration of the needs of the patient for whom even the very best is none too good, whether it is liked or not, the student nurse insistently is demanding improved and advanced educational opportunities that will permit her not only to care for the sick at the bedside, but as well capably to carry on vital far-reaching public health and welfare activities and to hold positions of trust, management and research in institutional, educational, governmental and social service.

Conceding what just has been mentioned then the cultural education of the nurse must be greater than formerly, and within obvious limits the wider the better. It, therefore, follows that on its present established basis, the hospital should not be asked to furnish this part of nurse education. One clear-headed, far-sighted physician—a hospital manager—considers that "the training of a nurse is practically a university business, or a business which belongs to a school of technology up to the time when the nurse begins to take her practical training." While, the superintendent of a very successful nurse education school is "convinced that with the increasing number, not only of young women going through the high school, but completing the four years at college, it ought to be quite possible to meet the nursing needs through a professional preparation imposed upon at least four years of high school."

Now, it appears that after 23 years of operation of the New York State Registration Law many institutions are woefully short in supplying minimum necessary educational facilities for the training of professional nurses. It, therefore, would seem that the present system of nurse education has become, not only antiquated, but markedly inadequate, and, that soon radical changes must be made, not backward but forward.

Considered from the standpoints of the public and the hospital, the hospital only should develop experience in nursing care of the sick at the bedside by applying principles and practice of nursing taught in extra-hospital schools. Under the present very limited instruction required by the education law, such extra hospital education easily could be given in the high schools and academies of the State in a vocational course preparatory to entrance to approved hospital training schools where expert bedside experience could be obtained on a "quid pro quo" basis of remuneration. The qualifying hospital would secure under-graduate resident nurses with theoretic instruction all finished. The economic loss from nurse-labor turnover, from wastage due to inexperience, and from lessened housing and maintenance charges would be no inconsiderable sum. The hospital would secure moderately experienced and efficient service from the very beginning, thus making possible a lessened personnel. While it easily is conceivable that the patients, the paramount issue, would receive more skilled and satisfying attention.

Dr Charles R. Mann, Director of the American Council on Education at the annual Congress on Medical Education, Medical Licensure and Hospitals at Chicago, February 15-18 1926, in discussing the defects of medical curricula suggested the use of what is known in

industry as "job specifications" for "application to the medical profession so that as far as possible students likely to succeed in medicine could be picked during their elementary and high school course and only those properly fitted for the study of medicine would be permitted to undertake it." It easily is conceivable that the suggested high school-preparatory-nurse course automatically would eliminate undesirable pupil nurses, whether from mental or physical incapacity or from romantic notions.

A survey of the various courses offered students in high and vocational schools and in academies does not make the possible establishment of nurse education courses appear at all Utopian.

A tentative scheme for nurse education through the high school, the hospital and the university would have the pupil begin at about age 13-14 and become eligible to contest the New York State examinations for R N at about age 22-23. If the pupil desired to take university degrees in nursing, the high school diploma secured at age 18-19 would admit to courses securing at age 23-24 a diploma as Bachelor of Science in nursing, or, as a Public

Health Nurse. If the pupil desired further education then master and doctor degrees in nursing could be obtained after 1-2 to 4-5 more years.

During the high school period experience could be obtained by extra-mural affiliation with creches, orphan asylums and homes for cripples and for old folks. Later experience could be gained in hospitals, general and special, and in field work in welfare organizations, somewhat after the way shown in a table marked "E" accompanying this communication.
